Abstract: - In this work an N-state Markov Chain model is attempted to validate, which is used to generate an attenuation time series. The model is applicable for estimating the CCDFs (complement cumulative distribution function) of attenuation. The state transition probability parameters of the model is determined from fade slope statistics of attenuation. The conditional probability density function of fade slope is estimated with a Gaussian distribution function.

Key-Words: - Attenuation modeling, N-state Markov Chain model, Fade Slope modeling, CCDF of attenuation estimation

1 Introduction
Wave propagation at high carrier frequencies (above 10 GHz) is highly influenced by precipitation especially by rain. To investigate wave propagation phenomena a rain attenuation and weather data measurement system was established. Currently in Hungary a number of point-to-point millimeter wave link operating in the frequency bands of 13, 15, 23 and 38 GHz. The received IF signal powers are collected with the meteorological data together using weather stations at different locations for data collection. In our previous work an N-state Markov Chain model is used to generate a rain attenuation time series [1],[2]. The model is applicable for estimating the CCDFs (complement cumulative distribution function) of attenuation. The model parameters were derived from fade slope statistics of attenuation, which was determined from a Gaussian fade slope model. In this contribution this model is validated on other terrestrial microwave links.

2 The Considered N-state Markov Chain Model
In the considered N-state Markov Chain model there are many states according to the attenuation levels [1],[2],[3]. Because each state represents an attenuation level with 0.05 dB resolution, this model can generate time series, which will be quantized with resolution 0.05 dB. The number of states in the model is dependent for the maximum attenuation, which will occur in the time series to generate. The schematic representation of the model is depicted in Fig.1 [3]. In Fig.1 the number of states is N, the state probabilities \( z_i \) gives the probability of \( A_i \) attenuation level, and the state transition probabilities \( p_{ij} \) can arranged into the transition probability matrix \( P \).

![Fig.1. The schematic representation of the N-state Markov Chain model with state probabilities and state transition probabilities](image)

3 Calculating Of Model Parameters Using Fade Slope Statistics
The state transition probability parameters of the model can be determined from the fade slope statistics of attenuation measurement \( A(t) \) of the examined terrestrial microwave link. Fade slope is a relevant second-order statistics for planning purposes. Fade slope \( \zeta \) indicates the rate of change of attenuation, so gives the gradient (in dB/s) of the fading at a given fade threshold (1) [1].

Determining the \( P(\zeta | A_i) \) (CPDF, conditional probability density function) of fade slope for every...
\[ p_{ij} \] probability of transition in the next second from state \( A_i \) to state \( A_j \) corresponds to the \( P(\zeta = (A_j - A_i)/2 | A_i) \) value. The details of this calculation method is described in [1].

\[ \zeta_{[dB/s]} = \frac{A(t+1) - A(t-1)}{2} \]  

In Fig.2 the \( P(\zeta | A_i) \) of fade slope is depicted for attenuation level 5 dB calculated on different terrestrial microwave links, which parameters are listed in Table 1.

Please notice, that the CPDFs of fade slope are very similar, so they more depend on the attenuation level than the parameters of a given link.

3.1 Calculating from a Gaussian fade slope model

We carried out, that we can estimate the CPDF of fade slope for different attenuation levels with a Gaussian distribution function (2) [2].

\[ P(\zeta | A) = \frac{1}{\sqrt{2\pi}\sigma_\zeta} e^{-\frac{1}{2}\left(\frac{\zeta}{\sigma_\zeta}\right)^2} \]  

where \( A \) is the attenuation in dB, \( \zeta \) is the fade slope in dB/s. Because of the characteristics of the fade slope, the expected value of the normal distribution is zero. The standard deviation parameter \( \sigma_\zeta \), which depends on the attenuation level can be estimated from the standard deviation of \( P(\zeta | A_i) \) of fade slope measured on either investigated microwave links. In our work we used the \( P(\zeta | A_i) \) of fade slope measured on HU11. This choice depends only on us, because of the similarity between the CPDFs calculated on different microwave link, but at the same attenuation level (Fig.2).
As obtained in Fig.3 and in Fig.4 the calculated attenuation dependent standard deviation of the conditional probability density of fade slope can be estimated by a power function. A well fitting power function was found for attenuation levels lower than 1 dB, and an other was found for higher attenuation levels (3).

\[
\sigma_s = \begin{cases} 
  a \cdot \left( \frac{A}{0.05} + 1 \right)^b , & A < 1 \text{ dB} \\
  e \cdot \left( \frac{A-1}{0.05} + 1 \right)^f + g , & A \geq 1 \text{ dB} 
\end{cases}
\]

where \( a, b, e, f, \) and \( g \) are experimental parameters; they values are listed in Table 2.

This Gaussian fade slope model fits to the CPDF of fade slope calculated from the HU11 measurement well for lower attenuation level as obtained in Fig.5.

At higher attenuation levels the Gaussian model fits also well (Fig.6), but because of the few available measured data at higher attenuation levels, the fitted Gaussian functions may not describe the measured fade slope well.

\[ P(\varsigma|A=0.5 \text{ dB}) \] 
\[ P(\varsigma|A=9 \text{ dB}) \]

4 Steady State CCDF Of The N-state Markov Chain Model

From the transition probability matrix of the general N-state Markov Chain model \( \mathbf{P} \), the CCDF \( P(A \geq A_i) \) of generated attenuation time series can be calculated with (4), where \( \mathbf{z} \) is the steady state probability vector [4].

\[
P(A \geq A_i) = \sum_{j=i}^{N-1} z_j , \quad \mathbf{z} = \mathbf{\Pi}^{\top} \cdot \mathbf{z} \quad (4)
\]

Fig.7. The CCDFs of the measured data (HU11) and of the generated time series. The \( p_{ij} \) parameters are derived from the Gaussian model.
Please notice in Fig.7, that the CCDF of attenuation measured on HU11 link can be estimated well, if the $p_{ij}$ parameters of the Markov model are derived from the Gaussian fade slope model described above.

5 Validating The Model

The transition matrix of the applied N-state Markov Chain model was derived from our Gaussian fade slope model, whose experimental coefficients were determined from the HU11 link measurement.

In this section the model is applied for three different microwaves links to estimate its annual CCDF of attenuation. These links are operating in the same frequency band, but with different length and locations in Hungary (Table 1).

On the investigated terrestrial microwave links the maximum value of the occurred attenuation are different.

By the transition matrix determination applying the Gaussian fade slope model the $\langle \sigma_s \rangle$ parameter must be calculated with (3) until the maximal attenuation value of the appropriate microwave link, whose CCDF is being estimated.

The annual CCDF of attenuation and the estimated CCDF of attenuation belong to the investigated links are depicted in Fig.8-10. Please notice, that the maximal attenuation supposed by the model equals to occurred maximal attenuation on the given link.

The logarithmic RMSE (root mean square error), which was calculated by (5) and (6), between the calculated and the estimated CCDFs are listed in Table 3.

\[
\varepsilon_i = \log(P_e(A \geq A_i)) - \log(P_c(A \geq A_i))
\]

\[
RMSE = \sqrt{\frac{1}{M} \sum_{i=1}^{M} \varepsilon_i^2}
\]

where $\varepsilon_i$ is the error, $P_e(A \geq A_i)$ and $P_c(A \geq A_i)$ are the values of the estimated and the calculated CCDFs at $A_i$ attenuation level and $M$ is the number of the examined attenuation levels.

As obtained from Fig.8 the estimated CCDF belongs to link HU36 fits to the calculated CCDF less. On the other hand the CCDF estimation for link HU52 is quite well (Fig.10), in this case the logarithmic RMSE is less than in case of HU11 (Table 3); however, the transition probability matrix of the N-state Markov Chain model is derived from the HU11 measurement.

6 Conclusion, Future Work
In this contribution we focused on validating a general N-state Markov Chain model, which is proposed for attenuation time series generation. The model parameters were derived from conditional probability density of fade slope, which was estimated by a Gaussian fade slope model for every attenuation level.

The attenuation dependent deviation parameter of the Gaussian fade slope model was determined from measurement performed on a terrestrial microwave link (HU11).

As validation of the general N-state Markov Chain model, this contribution shows how well the CCDF of the generated time series estimates the CCDF of annual attenuation time series measured on a given terrestrial microwave link.

A comparison was given of the CCDF of the generated time series (as a CCDF estimation) and of measured data belong to three different microwave link. We found, that this CCDF estimation can be quite good, but it can be quite bad too. The main reason of this difference, that the model parameters were determined considering only one measured attenuation time series.

We expect that the CCDF of the generated time series would estimate better the CCDF of the measured attenuation data on any terrestrial microwave link operating in the examined frequency band, if the attenuation dependent standard deviation parameter of the applied Gaussian fade slope model was derived considering several measured attenuation time series simultaneously.
