Abstract : — The main purpose of this study is to predict the real estate price in Taiwan efficiently. Neural networks and Support Vector Regression are applied and compared. Variables are first selected from previous research and then chose by stepwise procedure and trial-and-error methods. It is found that SVR with trial-and-error method performed the best with MAPE=4.466% and $R^2=0.8540$. In addition, Rediscount rate, Money supply, and Price of last month are the three common variables for both BPNN and SVR.

Keyword : - Forecasting, Real estate, Back propagation neural network, Data mining, Support Vector Regression

1 Introduction
Economic bubbles were born and burst in many countries since 90’s, causing their economic growths went up and down dramatically. Taiwan in 1990s and United States in 2008 are typical examples. One of the main factors in formation and rupture of these economic bubbles is the price volatility of real estates (Kaashoek and Dijk, 2002). One would be prepared and make correct decision when the prices vary if mastering the price trend. Therefore, to capture the changing tendency and then predict the trend of real estate price precisely has been an important research direction for Governments and researchers.

Traditional prediction in the real estate price is to build a regression model, which is usually confined by certain function and thus does not always provide a desired solution (Tay and Ho, 1992; Do and Grudnitski, 1992 ). Another common tool since 90s is the neural network, which is capable of dealing with nonlinear problems. It also has advantages in requiring less pre-assumptions and having learning ability, as long as enough data are supplied (Tsoukalas and Uhrig, 1997; Kuan and White, 1994; Lin and Lee,1996). Some successful
applications are reviewed below. For examples, Do and Grundnistski (1992) applied neural networks and multi-regression analysis to test the models with 105 data of house trading, resulting in absolute error of 6.9% and 11.3%, respectively. Tay and Ho (1992) adopted the same methods to predict prices of departments in Singapore using 822 training data and demonstrated that neural networks performed better than regression analysis. Similar applications can be found in McCluskey et al. (1997), McGreal et al. (1998), and Wong et al. (2001). A common character in these papers is that Back Propagation Neural Network (BPNN) is the primal prediction tool. However, some researchers argued that BPNN has some disadvantages such as requiring large amount of data, hard to find stable optimal solution, and possible over-fitting problems (Worzala et al. 1995). But it is still a popular and valid method in many applications.

As a recent popular method, Support Vector Machine (SVM) was proposed by Vapnik (1995) with principles of empirical risk minimization (ERM) and Structural Risk Minimization (SRM), which ensure the unique optimal solution without over-fitting. SVM was first applied in recognitions of handwriting, image, and voice. Vapnik et al. (1997) further proposed Support Vector Regression (SVR) for predictions and led to many successful applications in different aspects, such as prediction in stock market (Trafalis and Ince, 2000), Futures Contract (Tay and Cao, 2001), seasonal GDP of industrial machinery (Pai and Lin, 2005), and Tokyo Nikkei 225 index (Huang, Nakamori and Wang, 2005). With these successful applications, it is our attempt to apply BPNN and SVR to predict the price of real estates.

2 Data and Research methods
It is now widely accepted that the price of real estate represents the real estate climate in many aspects. In Taiwan, the price of Taipei’s real estate differs significantly from the rest of cities, as Taipei city is the capital city. Therefore, data from other well-developed cities are collected to represent the real estate climate.

The data adopted in this study are mainly purchased from Taiwan’s Real Estate Portal. Data are collected and averaged by month, including Taipei county, Taichung city and county, and Kaohsiung city and county. The time of collected data is from 2004/1 to 2008/12. Figure 1 shows the increasing trend of Taiwan real estate price by month, the Y-axis is the prices in 10K.

![Figure 1. The trend of Taiwan real estate price](image)

In this study, Back Propagation Neural Networks (BPN) and Support Vector Regression (SVR) are applied to perform the prediction. Since these methods are now widely applied in many domains, only brief review is provided below.

The BPNN is feed-forward a network with backward error propagation that learns from examples. The advantages of BPNN include the ability of dealing with nonlinear data, error-tolerance, parallel computing, and being a universal approximator, as long as enough data are available. Detailed description and be found in Hornik (1989).

SVR is originally from support vector machine (SVM) proposed by Vapnik (1995) and is modified for regression in 1997 (Vapnik et al., 1997). The
SVR model produced by support vector classification depends on a subset of the training data. SVR model can also cope with nonlinear data and has only a unique optimal solution with each set of kernel parameter and soft margin parameter. In our study, SVR is combined with Grid algorithm for the best combination of parameters.

Both Mean Absolute Percentage Error (MAPE) and Coefficient of Determination ($R^2$) are adopted as the indices of efficiency to compare the three methods.

### 3 Data Analysis and Comparison

#### 3.1 Variable Selection

According to Real Estate Cycle Indicators of Taiwan Ministry of Interior (in Chinese), the effective variables can be classified into three categories: leading indices, simultaneous indices, and lagging indices as shown in Table 1.

For prediction, only leading and simultaneous variables are considered in this research. Among the variables list in Table 1, due to the difficulty of obtaining data, three variables, namely Volume index of prime land, Residential use rate, and Building Permit of Residence, are not included. In addition, Benchmarking lending rate is replaced by Rediscount rate; Money supply includes $M1a$, $M1b$, and $M2$. As a result, 11 variables plus “price in last month” (namely, $t-1$ price) are included in our models. These variables are: Gross Domestic Product, Rediscount rate, The Standard Unit Price of New Cases, Money supply $M1a$, Money supply $M1b$, Money supply $M2$, New House-purchasing Loans, Consumer Price Index, Construction stock indices, Movement of Loans for Construction, $t-1$ price.

Stepwise procedure and trial-and-error methods are applied for the variable selection in BPNN. The results are as shown in Table 2. From Table 2, it can be found that Rediscount rate and $t-1$ price are common variables of both selecting methods. Also, the best prediction is by trial-and-error selection with $R^2$ of 0.7382.

Repeat the same procedure using SVR, the result is as shown in Table 3. Again, the common variables are Rediscount rate and $t-1$ price. Money supply is also a common variable since $M2$ and $M1a$ are closely related: $M2 = M1a + current savings account + Quasi-money$. The best $R^2$ is 0.8540 using trial-and-error, which is better than using BPNN. It can be observed from Figure 2 that most predictions of SVR are better than BPNN.

### 4 Conclusions

The main purpose of this study is to predict the real estate price in Taiwan efficiently. Neural networks and Support Vector Regression are applied and compared. Variables are first selected from previous research and then chose by stepwise procedure and trial-and-error methods. It is found that SVR with trial-and-error method performed the best with MAPE = 4.466% and $R^2 = 0.8540$. That is, stepwise regression is efficient but not the best variable selection method with both BPNN and SVR. Possible reason is that the existence of nonlinearity in price prediction.

In addition, Rediscount rate, Money supply, and Price of last month are the three common variables for both BPNN and SVR. In our opinion, these variables are the most important variables in predicting real estate prices.

Furthermore, to have the best prediction using SVR, variables of Gross Domestic Product, Rediscount rate, The Standard Unit Price of New Cases, Money supply $M1a$, New House-purchasing Loans, $t-1$ price should be included in the model.
