Abstract: - Steganography is a form of security technique through obscurity; the science and art of hiding the existence of a message between sender and intended recipient. Steganography has been used to hide secret messages in various types of files, including digital images, audio and video. The three most important parameters for audio steganography are imperceptibility (indicated as PSNR), payload (bit rate or capacity), and robustness. Any technique which tries to improve the payload or robustness should preserve imperceptibility. The noise which is introduced due to bit modification would limit payload. This paper presents the correlation between PSNR and bit per sample rate that is calculated in an experimental way.

Key-Words: - artificial intelligence; multimedia security; digital data hiding; steganography; watermarking

1 Introduction
Steganography and watermarking techniques embed information in a digital media in a transparent manner. Steganography is a technique for covert information, but digital watermarking may not hide the existence of the message from third persons [1-5].

Watermarking usually requires robustness to withstand against attacks intended to remove or destroy the hidden message from the watermarked media as well as preserving the carrier signal quality. This makes digital watermarking appropriate for those applications where the knowledge of a hidden message leads to a potential danger of manipulation [6-13].

The most well-known examples of steganography go back to ancient times when Histiaus shaved his slave’s head, and then he tattooed a message on his scalp. After that his hair had re-grown the tattooed message was disappeared. He was going to call his men to attack to the Persians [14-22].

Steganography is the study of methods for hiding the existence of secondary information in the presence of primary information in a way which neither affects on the size nor results in perceptual distortion. The secondary information is referred to as hidden message, hidden file or hidden information while primary information is referred to as carrier, host or original signal, before embedding and stego signal, file, bit stream or sequence, after embedding [23-30].

Watermarking techniques are principally context-specific, that means, the algorithms must be designed regarding the media type of the data to be watermarked. Therefore, watermarking indicates a specific application of steganographic techniques. Specifically, the additional requirement for robustness of digital watermarks against attacks or manipulations during the data processing entails a lower payload of the watermarking methods compared to steganographic algorithms [31-36].

2 PSNR of Different Bit per Sample Rates
This section presents the result of embedding twelve messages into twelve different music files in different bit per sample rates. The embedded messages were carefully selected to be in the suitable size to cover the hosts completely, to make the PSNR calculation accurate. Also, host files were selected from twelve different genres intentionally to make the result more general.

The focus of this research is the audio steganography, particularly with respect to WAV files. This format of audio file is selected because that is the original format of other formats. In other words, the audio files which have other formats, either are converted from WAV format, or can be easily converted to WAV format.
2.1 Obtained PSNR for one bit per sample rate

Twelve different messages were embedded into twelve different hosts with a payload of one bit per sample. The size of message files, host files and obtained PSNR are tabulated in Table 1.

</tbody>
</table>

As Figure 5 shows, the obtained PSNR for all tested music files is almost between a range of 26 db and 30 db.

4 Conclusion

As Figure 6 shows, twelve different genres of music files with WAV format were selected. Then GSBAS was run with five different bit rates. Message bits were different and had different sizes, which was important and was the constant is that selected messages have a size which covers throughout their host. That guarantees the obtained PSNRs are accurate. This study shows that for a specified bit rate almost a specified PSNR yields which is calculated in average in last row. In the other words, if the size of message file is almost the same as host files capacity, the PSNR of embedding depends on the bit per sample rate. Different host and different message file will have a little effect on PSNR.
