Abstract:- The primary objective of this study is to determine the optimum hybrid system able to supply the necessary electrical load of a typical community in a remote location in Greece. The renewable energy systems were comprised of different combinations of PV modules and wind turbines supplemented with battery storage. A software tool, HOMER is used for the analysis. The hybrid system analysis has showed that the minimum cost of energy is 0.268 $/kWh with 10% annual capacity of shortage. The optimum hybrid system comprised of 1.5 kW PV array, 1 wind generator, 3 kW power converter, and 14 storage batteries.

Key-words:- Hybrid Wind/PV/Battery system, Renewable energy, Net Present Cost (NPC)

1. Introduction

In remote areas, the cost of grid extension is prohibitive and the cost of fuels increases drastically with the remoteness of location. Renewable energy sources, such as photovoltaic, wind energy, or small-scale hydro, provide a realistic alternative to engine-driven generators for electricity generation (Nandi and Ghosh, 2009; Dihrab and Sopian, 2010). The individual fluctuation of the wind and solar resources can be overcome using hybrid renewable energy systems with battery backup. Applications of hybrid systems vary from small power supplies for remote home providing electrical energy to village electrification for remote communities. There is adequate research work on hybrid energy systems (Nandi and Ghosh, 2009; Dihrab and Sopian, 2010; Balamurugan et al., 2011; A.H. Al-Badi et al., 2011).

A basic schematic diagram of a hybrid Wind/PV energy system with battery storage is provided in Fig. 1. The system consists of PV generator, a wind generator, a battery storage system, a power converter that is able to meet the consumption peak load demand, charge controllers for wind turbine and PV modules to supply energy to the batteries at the appropriate voltage. As seen in Fig. 1, the battery bank stores energy when excess wind and solar energy is available and releases it for later lacking loads. The amount of the electricity produced via the system depends on the global solar radiation and the wind speed in general.

The Evros Prefecture is the northernmost of the prefectures of Greece. It is located in the eastern and northeastern part of the region of Thrace, and borders Turkey at the Evros River. Evros borders Bulgaria to the north and the northwest. The Rhodope prefecture borders it to the west. At the Rhodope sierra there is a small isolated village with name Plaka (Fig. 2 from the Google maps) which is far from the power grid and consequently will not be connected to it. Taking advantage of the good solar and wind potential of Plaka (latitude 40°53 N, longitude 25°43 E), a stand-alone hybrid Wind/PV system is proposed in order to meet the electricity demand of remote consumer.
The objective of this work is to present the results of a feasibility analysis of using renewable energy systems (PV/Battery, Wind/Battery, hybrid PV/Wind/Battery) for electrification of a typical isolated rural household in Plaka. In view of the fact that all areas in Greece have high irradiation level and the Plaka is situated in a mountain with high wind speeds, the necessary energy requirements may be obtained from renewable energy conversion systems such as wind turbines and PV panels. The overwhelming majority of the articles study the small or larger remote Greek islands; however, the present article is the first, which refers in the East Thrace (the most distant main land area in Greece). The area has one of the lowest standards of living in Greece.

Financial and economic crisis in Greece has changed the data on the field of the diesel price. On October 2009 the diesel price in Greece was approximately 0.8 €/L, however with rising fossil fuel prices and mainly with the new taxes today (December 2011) the diesel price costs more than 1.45 €/L (www.ypeka.gr). Coinstantaneously new taxes and the slashing of salaries has changed the standard of living for many people in Greece, so the economic feasibility of diesel generators not only in the case study but in all Greece remote areas is debatable. In this paper, the present investigation carries out a detailed techno-economic analysis simulations using HOMER (Hybrid Optimization Model for Electric Renewables) software (HOMER, 2011). HOMER is a modelling tool that facilitates design of standalone electric power systems. Many investigators have used Homer in order to find the optimum hybrid system (A.H. Al-Badi and H. Bourdoucen, 2011; Balamurugan et al., 2011; I. Baniasad Askari and M. Ameri, 2012, Karakoulidis et al., 2011). Analysis with HOMER requires information on resources, control methods, energy storage medium and economic constraints. The assessment criterions of the analysis are the Cost Of Energy (COE) and the Net Present Cost (NPC).

HOMER defines the levelized COE as the average cost/kWh of useful electrical energy produced by the system. To calculate the COE, HOMER divides the annualized cost of producing electricity by the total useful electric energy production. The equation for the COE is as follows:

\[
COE = \frac{C_{\text{ann,tot}}}{E_{\text{prim,AC}} + E_{\text{prim,DC}} + E_{\text{grid,sales}}}
\]

where \(C_{\text{ann,tot}}\) is the total annualized cost ($/yr), \(E_{\text{prim,AC}}\) is AC primary load served (kWh/year), \(E_{\text{prim,DC}}\) is DC primary load served (kWh/year), \(E_{\text{grid,sales}}\) is total grid sales (kWh/year). HOMER is primarily an optimization software package, which simulates varied renewable energy sources system. HOMER displays a list of configurations; sorted by NPC is the present value of all the costs that it incurs over its lifetime, minus the present value of all the revenue that it earns over its lifetime. HOMER calculates the total NPC using the following equation (NREL, 2011):

\[
C_{\text{NPC}} = \frac{C_{\text{ann,tot}}}{CRF(i, R_{\text{proj}})}
\]

where \(CRF\) is the capital recovery factor, \(i\) is the interest rate (%) and \(R_{\text{proj}}\) is the project lifetime (yr). The \(CRF\) is given by:

\[
CRF = \left(1 + i\right)^{R_{\text{proj}}}\left(\frac{1}{\left(1 + i\right)^{R_{\text{proj}}} - 1}\right)
\]

2. Meteorological Data

In order to calculate the performance of a hybrid Wind/PV system it is necessary to collect the meteorological data for the site location under consideration. The CRES (Centre for Renewable Energy Sources and Saving) is a source for these data (www.cres.gr). CRES is the Greek national entity for the promotion of renewable energy sources, rational use of energy and energy conservation.

The annual energy generated from wind turbines \(W_{\text{elec}}\), is given by the equation

\[
W_{\text{elec}} = \sum_{t=1}^{N_{\text{h}}} N_{\text{tr}} P_{\text{tr}} (V_{t})
\]

where \(t\) is the hour of the year, \(N_{\text{tr}}\) is the number of turbines at the site, \(P_{\text{tr}}\) is the power output as function of the average wind speed over a given hour, and \(N_{\text{h}}\) is the number of data hour in the year (Reichling and Kulacki, 2008). The wind power output is given by

\[
P_{\text{tr}} = n_{\text{tr}} \times n_{\text{p}} \times 0.5 \times p_{\text{a}} \times C_{\text{p}} \times A \times V_{t}^{3}
\]

where \(V_{t}\) the wind velocity, \(p_{\text{a}}\) the air density, \(C_{\text{p}}\) the power coefficient of wind turbine, \(A\) the wind turbine swept area, \(n_{\text{tr}}\), \(n_{\text{p}}\) the wind turbine and generator efficiency, respectively, as obtained from the manufacturers’ data.

The monthly average wind speeds for the period 1951–2001 are presented in Fig. 3A. Generally, the cut-in wind speed of most of the wind generators ranges from 3 to 4 m/s. The wind duration analysis points to that the wind speeds are more than 3 m/s for about 85.2% and more than 4 m/s for about 75% (at 10 m height) of the time during the year. As it can be seen, wind speeds are generally higher during the months November to March as compared to other months. This indicates that a wind generator produce more energy during winter. Notably, the data also shows that there is a considerable variation of the monthly average wind speed during summer.

The annual output power of the PV generator \(S_{\text{elec}}\) can be calculated by the equation

\[
S_{\text{elec}} = \sum_{t=1}^{N_{\text{t}}} n_{\text{solar},t} A_{\text{solar}} G_{t}
\]
where $G_t$ is the hourly insulation in Wm$^{-2}$, $A_{solar}$ is the fixed area of the solar field, and $n_{solar,t}$ is the solar conversion efficiency for a given hour of day during a given month (Reichling and Kulacki, 2008). If we choose that the effect of temperature on the PV is negligible HOMER uses the following equation to calculate the output of the PV array:

$$P_{PV} = Y_{PV} f_{PV} \frac{G_t}{G_{T,STC}}$$  (7)

where $Y_{PV}$ is the rated capacity of the PV array, meaning its power output under standard test conditions [kW], $f_{PV}$ is the PV derating factor [%], $G_t$ is the solar radiation incident on the PV array in the current time step [kW/m$^2$] and $G_{T,STC}$ is the incident radiation at standard test conditions [1 kW/m$^2$]. The total annual electrical output of the hybrid system can then be calculated as the sum of $S_{elec}$ and the $W_{elec}$ values.

The monthly mean values of the global solar radiation (GSR) are shown in Fig. 3B. It represents the monthly average daily GSR and monthly average daily clearness index. The case study area has special concern because has excellent wind potential, comparable with the famous Greek islands but less solar radiation. There are many other similar places in Greece like Epirus and East Macedonia, which have excellent wind potential but the solar potential is 25% less than the Aegean Archipelagos islands. Since measured hourly solar radiation data is rarely available, it is often necessary to use HOMER’s capability to generate synthetic hourly solar data from monthly averages. The algorithm that HOMER uses to synthesize solar data is based on the work of V. A. Graham and Hollands (Graham and Hollands, 1990). This algorithm produces realistic hourly data and it is easy to use because it requires only the latitude and the monthly averages.

3. Load and energy characteristics of the region

The load characteristic is critically important to the system optimization. The total daily consumption of a typical household is in the region of 15.15 – 15.4 kWh (Table 1) (Mantzari, 2009). Unfortunately measured hourly load information over the year in Plaka was not available and the size and shape of load profile fluctuate from hour to hour and from day to day. For this reason, on a daily and hourly basis a 15% noise level has been added to the calculated load with the purpose of randomize the load profile and make it more realistic. This has magnified the annual peak load to 5.1 kW.

4. The proposed autonomous hybrid Wind/PV/Battery system

The initial capital, operation and maintenance (O&M) costs of PV modules were determined based on the current prices of PV modules in Greece and are depicted in Table 2. The derating factor was taken as 0.9 and PV panels are mounted at a fixed slope and azimuth. WES 5 Tulipo wind turbine is considered

with rated power of 3 kW, has 5 m rotor diameter and 6.25 m of tower. The power curve of a WES 5 Tulipo wind turbine is shown in Fig. 4 (www.windenergysolutions.nl). The battery capacity and type were chosen from batteries specified in HOMER, Trojan T-105 (www.trojan-battery.com) are considered in the models. The function of the power converter is to maintain the flow of energy between the AC and DC components. Different sizes of converter (kW) were used in the present study and the lifetime of a unit was considered to be 25 yr with an efficiency of 90%. The characteristics and the cost data of the wind machine, batteries, and power converter considered in this study are also depicted in Table 2 (Hrhayshat, 2009; Nandi and Ghosh, 2010; Demiroren and Yilmaz, 2010; Türkay and Telli, 2011). The proposed hybrid Wind/PV/Battery system consists wind turbines, solar PV array, battery bank and power converter. Its schematic diagram is shown in Fig. 5. The system control parameters used in this investigation are summarized in Table 3. The project life time has been considered to be 25 yr and the annual real interest rate has been taken as 6%.

5. Results and discussion

**PV/Battery system:** In this system, PV panels supply entire load. The most feasible PV/Battery system comprised of 6 kW PV arrays, 54 kWh storage batteries in addition to 4 kW converter. According to the HOMER calculations the PV panels produces 10176 kWh/yr. NPC of the system is found as 36607 $ and 0.559 $/kWh is the COE (Table 4). As mentioned previously, the monthly average of solar radiation at Plaka is high during summer months as compared to the other months. This means that the PV panels produce more power in summer and lower the other months especially during the months from November to January.

**Wind/Battery system:** In this case, the optimum Wind/Battery composed of 2 WES 5 Tulipo wind turbines, 24.3 kWh storage batteries and 3 kW of power converter. This system uses 100% renewable energy comes from wind turbine (19358 kWh/yr). A comparison between the best Wind/Battery and PV/Battery(Table 4) systems shows that the first has about the half NPC and COE (19301 $ and 0.292 $/kWh, respectively). The wind turbines power output daily profile at Plaka presents significant fluctuation owing to the considerable variation of the monthly average wind speed.

**Wind/PV/Battery system:** Numerous simulations for various scenarios have been made by considering different combinations of wind generators and PV panels with hybrid systems. Based on the HOMER modelling, the optimal system for a typical household in Plaka is a hybrid Wind/PV/Battery system, with 1.5 kW of solar, a 3 kW wind generator, 18.9 kWh of batteries and 3 kW of power converter. This “optimal” system uses 100% renewable energy in which 79% electricity comes from wind source (9679 kWh/yr) and 21% electricity comes from solar radiation (2544 kWh/yr) with an annual capacity of shortage 10%. It is revealed that wind energy is advantageous in Plaka. The annual electricity production from the optimal hybrid system is 12223 kWh. There are no CO₂ and SO₂ emissions as there is no diesel generator. The comparison among the optimized Wind/PV/Battery system with Wind/Battery and PV/Battery system is given in Table 4. The optimization results show that the optimal Wind/PV/Battery system has lowest NPC (17879 $) with COE 0.268 $/kW. From the Table 4 it is clear that the optimized Wind/PV/Battery system reduces the COE about 7% and 51% compared with Wind/Battery and PV/Battery respectively. The total costs of each component are shown in Fig. 6A. Fig. 6B shows the average monthly electrical production.

In order to give a general overview of the situation, the results obtained from the sensitivity analysis in the form of a sensitivity graph (Türkay and Telli, 2011). Fig. 7 exhibits the sensitivity analysis in term of wind speed and the global solar irradiation. In the present case, wind speed (5, 6, 6.5, 7, 8 and 9 m/s) and GSR (4, 4.25, 4.58, 4.8 and 5 kWh/m² per day) were used as sensitivity variables. In winds above 8.45 m/s PV is eliminated from the system. However, the Wind/PV/Battery system becomes competitive below 8.45m/s.

6. Conclusion

In the present study, a techno-economic feasibility of
stand-alone, renewable energy systems to meet the electricity requirements of a typical remote village of Greece was investigated. HOMER was used for the analysis, and viability was determined based on NPC and COE. From this study, it is clear that the optimized Wind/PV/Battery hybrid system is more cost effective compared to Wind/Battery or PV/Battery systems for the load with 10% annual capacity of shortage. Wind and solar energy resources at Plaka have shown that an optimized Wind/PV/Battery can serve a typical remote settlement electricity demand with COE of 0.268 $/kWh. Generally, the results from the sensitivity analysis showed that the maximum electricity comes from wind, which predicts that wind is more feasible than the solar at the site. In such system 21% electricity comes from solar resource and 79% electricity comes from wind resource, the hybrid of the two energy resources reduces the COE of 7% and 51%, respectively, in comparison with Wind/Battery and PV/Battery combinations. The monthly average electricity production of the most feasible hybrid system showed that higher electricity production is noticed during the winter months (November–December) and on August as compared to other months.
