Abstract: This paper presents an intelligent adaptive control system (IACS) using a recurrent functional-link-based Petri fuzzy-neural-network (RFLPFNN) for induction motor (IM) servo drive to achieve high dynamic performance. The proposed IACS comprises a RFLPFNN controller and a robust controller. The RFLPFNN controller is used as the main tracking controller to mimic an optimal control law while the robust controller is proposed to compensate the difference between the optimal control law and the RFLPFNN controller. Moreover, the structure and parameter-learning of the RFLPFNN are performed concurrently. Furthermore, an on-line parameter training methodology, which is derived based on the Lyapunov stability analysis and the back propagation method, is proposed to guarantee the asymptotic stability of the IACS for the IM servo drive. In addition, to relax the requirement for the bound of minimum approximation error and Taylor higher-order terms, an adaptive control law is utilized to estimate the mentioned bounds. A computer simulation is developed and an experimental system is established to validate the effectiveness of the proposed IACS. All control algorithms are implemented in a TMS320C31 DSP-based control computer. The simulation and experimental results confirm that the IACS grants robust performance and precise response regardless of load disturbances and IM parameters uncertainties.

Key-Words: Functional-link neural-networks (FLNNs), intelligent control, indirect field-orientation control (IFOC), induction motor, Lyapunov satiability theorem, Petri net (PN), fuzzy-neural-network, robust control.

1 Introduction

Induction motors (IMs) have many advantageous characteristics such as high robustness, reliability and low cost compared with DC motors. In the last two decades, field-oriented control has become the preferred method used in the control of high performance IM drives. The objective is to obtain a torque dynamic similar to that of a separately excited DC motor. Therefore, IM drives are frequently used in high-performance industrial applications which require independent torque and speed/position control. Induction motors also possess complex nonlinear, time-varying and temperature dependency mathematical model. However, the control performance of the IM drives is sensitive to the motor parameter variations, especially the rotor time constant, which varies with the temperature and the saturation of the magnetizing inductance. In addition, the performance of IM drives is still influenced by uncertainties, such as mechanical parameter variation, external disturbance, unstructured uncertainty due to non ideal field orientation in the transient state and unmodeled dynamics. From a practical point of view, complete information about uncertainties is difficult to acquire in advance [1]-[2]. Therefore, in recent years much research has been done to apply various approaches to attenuate the effect of nonlinearities and uncertainties of IM servo drives to enhance the control performance [8]-[30]. Conventional proportional-integral-derivative (PID) controllers are widely used in industry due to their simple control structure, ease of design and implementation [3]-[7]. However, the PID controller cannot provide robust control performance because the IM servo drive system is highly nonlinear and uncertain. In addition, an objection to the real-time use of such control scheme is the lack of knowledge of uncertainties. Due to the existence of nonlinearities, uncertainties, and disturbances, conventional PID controller cannot guarantee a sufficiently high performance for the IM servo drive system. To deal with these uncertainties and nonlinearities and to enhance the control
performance, many control techniques have been developed for IM drive system, such as robust control [8]-[11], sliding mode control (SMC) [12]-[16], intelligent control [17]-[24], hybrid control [25]-[28], H∞ Control [29], [30]. These approaches improve the control performance of the IM drive from different aspects. Therefore, the motivation of this paper is to design and implement a suitable control scheme to confront the uncertainties existing in practical applications of an indirect field-oriented controlled IM drive.

The concept of incorporating fuzzy logic into a neural network (NN) has grown into a popular research topic. In contrast to the pure neural network or fuzzy system, the fuzzy-neural-network (FNN) possesses both their advantages; it combines the capability of fuzzy reasoning in handling uncertain information and the capability of NNs in learning from the process [31]-[35]. On the other hand, the recurrent fuzzy-neural-network (RFNN), which naturally involves dynamic elements in the form of feedback connections used as internal memories, has been studied in the past few years [34], [35]. In recent years, Petri net has found widely applications in modeling and controlling discrete event dynamic systems [36]-[39]. For the last decades, Petri net (PN) has developed into a powerful tool for modeling, analysis, control, optimization, and implementation of various engineering systems [40]-[46]. In [45], the concept of incorporating PN into a traditional FNN to form a new type Petri FNN (PFNN) framework for the motion control of linear induction motor drive is presented. In [46], the designed of a network structure by introducing PN into RFNN to form a dynamic Petri RFNN (DPRFNN) scheme for the path-tracking control of a nonholonomic mobile robot is presented.

One of the important points in the design of FNNs is the consequent part, which is able to impact performance on using different types. Two types of FNNs are the Mamdani-type and the Takagi-Sugeno-Kang (TSK)-type. For Mamdani-type FNNs, the minimum fuzzy implication is adopted in fuzzy reasoning. For TSK-type FNNs, the consequent part of each rule is a linear combination of input variables. It has shown that TSK-type FNN offer better network size and learning accuracy than Mamdani-type FNNs. In the TSK-type FNN, which is a linear polynomial of input variables, the model output is approximated locally by the rule hyperplanes. Nevertheless, the traditional TSK-type FNN does not take full advantage of the mapping capabilities that may be offered by the consequent part. Therefore, several researches [47]-[51] considers trigonometric functions to replace the traditional TSK-type fuzzy reasoning and also obtain better performance. In this view, the functional-link neural network (FLNN) has been proposed using trigonometric functions to construct the consequent part. The functional expansion increases the dimensionality of the input vector and thus creation of nonlinear decision boundaries in the multidimensional space and identification of complex nonlinear function become simple with this network. It seems to be more efficient to include the functional-link fuzzy rules into the PFNN. In [48]-[50], a functional-link-based fuzzy neural network for nonlinear system control is proposed., which combines a fuzzy neural network with FLNN. The consequent part of the fuzzy rules that corresponds to an FLNN comprises the functional expansion of the input variables.

With the above mention motivations, this paper presents the combination of PFNN and a FLNN to construct the consequent part, called recurrent FLNN-based PFNN (RFLPFNN) controller, for dynamic system identification and control of IM servo drive system. The proposed RFLPFNN is designed to improve the accuracy of functional approximation. Each fuzzy rule that corresponds to an FLNN consists of a functional expansion of input variables. The orthogonal polynomials and linearly independent functions are adopted as FLNN bases. An online learning algorithm, consisting of structure learning and parameter learning, is proposed to construct the RFLPFNN model automatically. The structure learning algorithm determines whether or not to add a new node that satisfies the fuzzy partition of input variables. Initially, the RFLPFNN model has no rules. The rules are automatically generated from training data by entropy measure. The parameter learning algorithm is based on back propagation to tune the parameters in the RFLPFNN model simultaneously to minimize an output error function. The advantages of the proposed RFLPFNN model are summarized as follows. First, the consequent of the fuzzy rules of the proposed RFLPFNN is a nonlinear combination of input variables. This paper uses the FLNN to the consequent part of the fuzzy rules. The functional expansion in RFLPFNN can yield the consequent part of a nonlinear combination of input variables to be approximated more effectively. Second, the online learning algorithm can automatically construct the RFLPFNN. No rules or memberships exist initially. They are created automatically as learning proceeds, as online incoming training data are received and as structure and parameter learning are performed. Third, as demonstrated in Section 3, the proposed RFLPFNN can solve temporal problems
effectively and is a more adaptive and efficient controller than the other methods.

This paper is organized as follows. Section 2 presents the indirect field-orientation control and dynamic analysis of the IM servo drive as well as the problem formulation. Section 3 presents the description of the intelligent adaptive control system for the IM servo drive. In addition, the design procedures and adaptive learning algorithms of the proposed RFLPFNN control system and the robust controller are described in details in Section 3. As well, the stability analysis of the proposed control system is introduced. The validity of the design procedure and the robustness of the proposed controller are verified by means of computer simulation and experimental analysis. All control algorithms have been developed in a control computer that is based on a TMS320C31 and TMS320P14 DSP DS1102 board. The dynamic performance of the IM drive system has been studied under load changes and parameter uncertainties. Numerical simulations and experimental results are provided to validate the effectiveness of the proposed control system in Section 4. Conclusions are introduced in Section 5.

2 Preliminaries

2.1 Induction Motor Dynamic Model and Indirect Field-Orientation Control

The dynamic model of the three-phase squirrel-cage Y-connected IM in d-q axis arbitrary reference frame is helpful to analyze all its characteristics for dynamic analysis and control [1], [2]. The voltage equation of the d-q model based on the stator currents and rotor fluxes is given by (1) while the electromagnetic torque is given by (2) while the mechanical equation of the IM is given by (3).

The electromagnetic torque can be expressed as:

\[
\begin{bmatrix}
V_{qs} \\
V_{ds}
\end{bmatrix} =
\begin{bmatrix}
R_s + L_s \frac{d}{dt} + \omega L_r \sigma \\
-L_m \frac{d}{dt} - \omega L_m \\
-L_m \frac{d}{dt} + \omega L_m \\
0
\end{bmatrix}
\begin{bmatrix}
i_{qs} \\
i_{ds}
\end{bmatrix}
+ \begin{bmatrix}
L_m \frac{d}{dt} + \omega L_m \\
\omega L_m
\end{bmatrix}
\begin{bmatrix}
\lambda_{ds} \\
\lambda_{qr}
\end{bmatrix}
\]

(1)

\[
T_e = \frac{3}{2} \frac{P_m}{2} \frac{L_m^2}{L_r} (\lambda_{ds} i_{qs} - \lambda_{qr} i_{ds})
\]

(2)

The mechanical equation can be expressed as:

\[
T_e = J_m \frac{d^2}{dt^2} \theta_t + \beta_m \frac{d}{dt} \theta_t + T_L
\]

(3)

The IFOC dynamics for the IM is derived from (1) and (2) respectively at the synchronous reference frame by setting \( \lambda_{ds} = 0 \), \( \frac{d\lambda_{ds}}{dt} = 0 \) and \( \omega = \omega_b \). The torque equation and slip angular frequency for rotor flux orientation are given in (4) and (5) while the voltage commands are given in (6)-(9) [2].

\[
T_e = 3 \frac{P_m}{2} \frac{L_m^2}{2} L_r \frac{d^2}{dt^2} \lambda_{ds}
\]

(4)

\[
\omega_b = \frac{1}{\tau_r} \frac{d}{dt} \lambda_{ds}
\]

(5)

\[
V_{qs} - e_{qs}^* = \left( L_s \sigma \frac{d}{dt} + R_s \right) i_{qs}
\]

(6)

\[
e_{qs}^* = \left( L_s \sigma + \frac{L_m^2}{L_r} \right) \omega_b i_{ds}
\]

(7)

\[
V_{ds} + e_{ds}^* = \left( L_s \sigma + \frac{L_m^2}{L_r} \right) \omega_b i_{qs}
\]

(8)

\[
e_{ds}^* = \left( L_s \sigma + \frac{L_m^2}{L_r} \right) \omega_b i_{ds}
\]

(9)

where \( V_{qs}, V_{ds}, i_{qs} \) and \( i_{ds} \) are the d-q axis stator voltages and d-q axis stator currents, \( \lambda_{qr} \) and \( \lambda_{dr} \) are the q-axis rotor flux and d-axis rotor flux, respectively. \( R_s, R_r, L_s, L_r, L_m \) are the stator resistance, rotor resistance, stator self-inductance, rotor self-inductance and mutual inductance, respectively. \( \omega_b, \theta_b, J \) and \( \beta \) are the rotor speed, the rotor position, the effective inertia and the friction coefficient, respectively. \( T_e, T_L, \tau_r, \tau_s \) and \( \omega_b \) are the electromagnetic torque, the load torque, the rotor time constant, the stator time constant and the slip angular frequency, respectively. \( e_{qs}, e_{ds}, \omega_b \) and \( \omega_e \) are the back emfs, the angular frequency of the arbitrary and the synchronous reference frames respectively. \( \sigma \) and \( P_m \) are the leakage flux coefficient and the number of poles, respectively. \( \tau_r = L_r / R_s \) and \( \sigma = \left( L_s L_r - L_m^2 \right) / L_s L_r \). The parameters of the IM are listed in Table (1).

The dynamic analysis of the IM may be expressed as follows. From (3) and (4), the mechanical dynamics can be simplified as:

\[
\dot{\theta}_t = \frac{J_m}{P_m} \frac{d}{dt} \theta_t + \frac{K_i}{P_m} \frac{d^2}{dt^2} \theta_t + \frac{2}{P_m} J_m \frac{d}{dt} T_L
\]

(10)

\[
\dot{T}_{e} = A_m \dot{\theta}_t + B_m U(t) + D_m T_L
\]

(11)

where \( U(t) = e_{qs}(t) \) is the control effort,

\[
K_i = (3 / 2) \left( \frac{P_m}{2} \right) \left( \frac{L_m^2}{L_r} \right) \omega_b^2,
\]

\[
A_m = -\left( \frac{\beta_m}{J_m} \right) \left( \frac{P_m}{2} \right),
\]

\[
B_m = K_i \left( \frac{J_m}{P_m} \right) \left( \frac{P_m}{2} \right) \quad \text{and} \quad D_m = -\left( \frac{P_m}{2} \right) \left( \frac{1}{J_m} \right).
\]

2.2 Problem Formulation

In order to efficiently control the rotor position of the IM drive system, an IACS is proposed to increase the robustness of the IFOC-IM drive system. The intelligent adaptive control system for the IM drive is shown in Fig. 1, in which the reference model is used as the closed loop transfer function of the drive system with the 2DOF I-PD position controller [20]. The proposed controller combines a RFLPFNN
controller and a robust controller. The RFLPFNN controller is utilized as the main tracking controller to mimic an optimal control law while the robust controller is designed with adaptive bound estimation algorithm to recover the residual of the approximation error via the RFLPFNN controller approximation. The hybrid control law is assumed to take the following form:

\[ U_{q_i}(t) = U_{\text{RFLPFNN}}^{q_i}(t) + U_{\text{RC}}^{q_i}(t) \]  \hspace{1cm} (12)

where \( U_{\text{RFLPFNN}}^{q_i}(t) \) is the RFLPFNN controller and \( U_{\text{RC}}^{q_i}(t) \) is the robust controller. In the following section, the description of the proposed control scheme and the stability analysis are introduced.

3 Intelligent Adaptive Control System (IACS)

In this section, the design procedure for the recurrent functional-link-based Petri fuzzy-neural-network controller in order to control the position of the IM is carried out. The proposed RFLPRFNN control scheme combines the merits of the Petri fuzzy-neural-network (PFNN), recurrent FNN and FLNN so that the robust control performance of the IM servo drive can be preserved. Define the tracking error vector as follows:

\[ E = [\theta^m_r(t) - \theta^*_r]^T = [e^m_{\theta} \ e^m_{\dot{\theta}}]^T \]  \hspace{1cm} (13)

where \( \theta^m_r(t) \) is the desired position command, \( \theta^*_r(t) \) is the actual rotor position, \( e^m_{\theta}(t) = [\theta^m_r(t) - \theta^*_r(t)] \) is the position error and \( e^m_{\dot{\theta}}(t) = [\dot{\theta}^m_r(t) - \dot{\theta}^*_r(t)] \) is the tracking position error change. Now, assume that the parameters of the IM servo drive system and the external load disturbance are well known, the optimal control law can be defined as follows:

\[ U^*_q(t) = B_m^{-1}[\ddot{\theta}^m_r(t) - A_m \dot{\theta}^*_r(t) - D_m \dot{T}_L(t) + KE] \]  \hspace{1cm} (14)

where \( K = [k_2 \ k_1] \), in which \( k_1 \) and \( k_2 \) are positive constants. Substituting (14) into (11) will yield

\[ e^m_{\dot{\theta}}(t) + k_1 e^m_{\theta}(t) + k_2 e^m_\theta(t) = 0 \]  \hspace{1cm} (15)

Suppose the control gain \( K \) is chosen such that all roots of the characteristic polynomial of (15) lie strictly in the open left half of the complex plane. This implies that the position tracking error will converge to zero when time tends to infinity, i.e. the IM servo drive states can track the desired trajectory asymptotically. However, the parameter variations of the IM are difficult to measure and the exact value of the external load disturbance is also difficult to know in advance for practical applications. Though, if the IM parameters are perturbed, the performance specified by (15) can not guarantee. Moreover, the stability of the IM servo drive may be destroyed. Therefore, to ensure the stability of the IM servo drive despite the existence of the uncertain dynamics and external load disturbance, a RFLPFNN controller is proposed to mimic the ideal control law and a robust controller is proposed to compensate the difference between the ideal control law and the RFLPFNN controller.

The control performance of the IM drives is sensitive to the parameter variations, external disturbance, unstructured uncertainty and unmodeled dynamics. Especially the rotor time constant, this varies with the temperature and the saturation of the magnetizing inductance. Therefore, conventional PID controller cannot guarantee a sufficiently high performance for the IM servo drive. To deal with these uncertainties and nonlinearities and to enhance the control performance, the IACS with RFLPFNN has been proposed for IM servo drive system.

The following subsections describe the structure of FLNNs and RFLPFNN models. The RFLPFNN adopted the FLNN and generating complex nonlinear combinations of input variables to the consequent part of the fuzzy rules. The details of these structures are given below.

3.1 Functional-Link Neural-Network (FLNN)

To improve the accuracy of the function approximation, an FLNN is adopted to implement the function expansion for the proposed RFLPFNN. The architecture of the FLNN is shown in Fig. 2, in which the functional link acts on an element of input variables by generating a set of linearly independent functions, i.e., function expansion. In the function expansion of the FLNN, basis functions such as trigonometric, Gaussian, or other orthogonal polynomials are feasible. In this paper, the trigonometric function is adopted since it forms a more compact representation than the Gaussian basis, and the sine and cosine functions can be computed more quickly. Moreover, better performance results when the outer product term is taken into account in the function expansion [47]. Therefore, for a two-dimensional input vector $x = [x_1, x_2]^T$ , the input variables are obtained using trigonometric functions and can be separated in the enhanced space $\Phi = [\phi_1, \phi_2, \ldots, \phi_M]^T = [1, x_1, \sin(\pi x_1), \cos(\pi x_1), x_2, \sin(\pi x_2), \cos(\pi x_2), x_1 x_2]^T$ , where $x_1, x_2$ is the outer product term. In the FLNN structure shown in Fig. 2, a set of basis functions $\Phi$ and a fixed numbers weight parameters $W$ represent $f_W(x)$. The theory behind the FLNN for multidimensional function approximation has been discussed in [47], [51]. Let $B = [\phi_1 \phi_2 \ldots \phi_M]^T$ be a set of basis functions to be considered as shown in Fig. 2. The FLNN comprises $M$ basis functions $\{\phi_1, \phi_2, \ldots, \phi_M\} \in B_M$ . The output of the FLNN is given by a linear sum of the $j$th node as

$$\hat{H}_j = \sum_{M} \omega_M \Phi_M (X) = \omega_1 \phi_1 + \omega_2 \phi_2 + \omega_3 \phi_3 + \cdots + \omega_M \phi_M$$

where $\chi \in \mathbb{R}^n$ , $X = [x_1, x_2, \ldots, x_n]^T$ is the input vector and $W_j = [\omega_1, \omega_2, \ldots, \omega_M]^T$ is the weight vector associated with the $j$th output of the FLNN. $\hat{H}_j$ denotes the local output of the FLNN structure and the consequent part of the $j$ th fuzzy rule in the RFLPFNN. Therefore, the matrix form of (16) can be expressed as

$$\hat{H}_j = W_j \Phi$$

where $\Phi = [\phi_1(x), \phi_2(x), \ldots, \phi_M(x)]^T$ is the basis function vector which is the output of the functional expansion block. In the RFLPFNN, the corresponding weights of functional link bases do not exist in the initial state, and the amount of the corresponding weights of functional link bases generated by the online learning algorithm is consistent with the number of fuzzy rules.

3.2 Structure of Recurrent Functional-Link-Based Petri Fuzzy-Neural-Network

This subsection describes the RFLPFNN, which uses a nonlinear combination of input variables (FLNN). Each fuzzy rule corresponds to a sub-FLNN, comprising a functional link. Fig. 2 represents the structure of the proposed RFLPFNN.

The RFLPFNN model realizes a fuzzy IF-THEN rule in the following form:

Rule $j$:

IF $x^j_b$ is $\tilde{A}^j_b$ and $x^j_c$ is $\tilde{A}^j_c$ \ldots and $x^j_i$ is $\tilde{A}^j_i$ \ldots and $x^j_n$ is $\tilde{A}^j_n$ \ldots THEN

$$\hat{H}_j = \sum_{M} \omega_M \Phi_M (X)$$

$$= \omega_1 \phi_1 + \omega_2 \phi_2 + \omega_3 \phi_3 + \cdots + \omega_M \phi_M$$

$$y_a = \sum_{k=1}^{N_f} \sigma_k^T \Psi_k \sum_{M} \omega_M \Phi_M$$

(18)
where $x_i^j$ and $\hat{y}_j$ are the input and local output variables, $\tilde{\alpha}_j^i$ is the linguistic term of the precondition part with a Gaussian membership function, $n$ is the number of input variables, $\omega_{z0}$ is the connective weight of the local output, $\phi_M$ is the basis function of the input variables, $M$ is the number of basis function, and the Rule $j$ is the $j$th fuzzy rule. The connective weight $\sigma_k^i$ is the output action strength of the $o$th output associated with the $k$th rule and $\mu_k^i$ represents the output of the rule layer. The operation functions of the nodes in each layer of the RFLPFNN model are described.

The architecture of the proposed six-layer RFLPFNN is shown in Fig. 2, which comprises the input layer (the $i$ layer), membership layer (the $j$ layer), Petri layer (the $p$ layer), rule layer (the $k$ layer), consequent layer (the $l$ layer) and output layer (the $o$ layer). The signal propagation and the basic function in each layer are introduced as follows.

1) Layer 1- Input Layer: The nodes in layer 1 transmit the input signals to the next layer. For every node $i$ in the input layer, the net input and the net output can be represented as:

$$y_i^1 = f_i^1(\text{net}_i^1(n)) = \text{net}_i^1(n) \quad i = 1, 2 \quad (19)$$

where $x_1^i = e_{m}^i(t)$, $x_2^i = e_{d}^i(t)$ and $y_1^i$ represents the $i$th input to the node of layer 1, $n$ denotes the number of iterations.

2) Layer 2- Membership Layer: Each node in this layer performs a membership function. The input of the membership layer can be represented by

$$h_i^j(n) = x_i^j(n) + \beta_i^j(n-1)\alpha_i^j \quad (20)$$

where $\alpha_i^j$ represents the weight of the self-feedback loop, $\beta_j(n-1)$ indicates the output signal of layer 2 in the previous time and is defined with Gaussian membership function as

$$net_j^i(h_i^j) = \left(\frac{h_i^j - \mu_i^j}{\sigma_i^j}\right)^2 \quad (21)$$

$$\beta_j^i[\text{net}_j^i(h_i^j)] = \exp[\text{net}_j^i(h_i^j)] = \exp\left[-\left(\frac{h_i^j - \mu_i^j}{\sigma_i^j}\right)^2\right] \quad (22)$$

where $\exp[\cdot]$ is the exponential function, $\mu_i^j$ and $\sigma_i^j$ are the mean and standard deviation of the Gaussian function in the $j$th term of the $i$th input variable $x_i$ to the node of this layer, $n_j$ is the number of linguistic variables with respect to each input.

3) Layer 3- Petri Layer: The Petri layer of the RFLPRFNN is used to produce tokens and also makes use of competition learning laws to select suitable fired nodes as follows

$$t_i^j = \begin{cases} 1, & \beta_i^j(\text{net}_j^i(h_i^j)) \geq d_{th} \\ 0, & \beta_i^j(\text{net}_j^i(h_i^j)) < d_{th} \end{cases} \quad (23)$$

where $t_i^j$ is the transition and $d_{th}$ is a dynamic threshold value varied with the corresponding error to introduced later.
4) Layer 4- Rule Layer: Each node \( k \) in layer 4 (rule layer) is denoted by \( \Pi \), which multiplies the incoming signals and outputs the result of the product. For the \( k \)th nodes:

\[
\text{net}_k = \left[ \prod_{i=1}^{n} \sigma^i_k \beta^i_k (\text{net}_j(h^i_j)), \ t^i_j = 1 \right.
\]
\[
0, \ t^i_j = 0
\]

From (22) and (24), we can obtain

\[
\psi_k = f_k(\text{net}_k) = \left[ \prod_{i=1}^{n} \sigma^i_k \exp \left( \frac{-\left( h^i_j - \mu^i_j \right)^2}{\sigma^i_k} \right) \right], \ t^i_j = 1
\]
\[
0, \ t^i_j = 0
\]

where \( \beta^i_k \) represents the \( j \)th input to the node of the rule layer, \( \psi_k \) represents the \( k \)th output of the rule layer; \( \sigma^i_k \), the connective weights between the Petri layer and the rule layer. These weights are assumed to be unity; and \( N_r \) is the total number of rules.

5) Layer 5- Consequent Layer: Nodes in this layer are called consequent nodes. The input to a node in layer 5 is the output from layer 4 and the other inputs are nonlinear combinations of input variables from the FLNN \( \tilde{H}_j \) as shown in Fig. 2. For such node

\[
y^i_j = \psi_k \tilde{H}_j = \psi_k \sum_{M} \omega_{M} \Phi_{M}
\]

\[
= \left\{ \sum_{M} \omega_{M} \Phi_{M} \prod_{i=1}^{n} \sigma^i_k \beta^i_k (\text{net}_j(h^i_j)) \right\}, \ t^i_j = 1, 0, \ t^i_j = 0
\]

where \( \omega_{M} \) is the corresponding connective weight of the FLNN and \( \Phi_{M} \) is the functional expansion of input variables. The functional expansion uses a trigonometric polynomial basis function, given by \( [x_1 \sin(x_1) \cos(x_1), x_2 \sin(x_2) \cos(x_2)] \) for two-dimensional input variables. Moreover, the output nodes of the FLNN depend on the number of fuzzy rules of the RFLPFNN model.

6) Layer 6- Output Layer: Each node in this layer corresponds to a single output variable. The output node in layer 6 integrates all of the actions from layer 4 and 5 and acts as a center of area defuzzifier.

\[
\text{net}_o = \sum_{k=1}^{N_r} \sigma^o_k \psi_k \sum_{M} \omega_{M} \Phi_{M}
\]

\[
y_o = f_o(\text{net}_o) = \text{net}_o \quad o = 1
\]

\[
\tilde{H}_j \sum_{k=1}^{N_r} \sigma^o_k \psi_k = \sum_{k=1}^{N_r} \sigma^o_k \psi_k \sum_{M} \omega_{M} \Phi_{M}
\]

\[
y_o = \frac{\sum_{k=1}^{N_r} \sigma^o_k \psi_k}{\sum_{k=1}^{N_r} \sigma^o_k \psi_k}
\]

where the connective weight \( \sigma^o_k \) is the output action strength of the \( o \)th output and \( y_o \) is the output of the RFLPFNN and \( N_r \) is the total number of rules.

The output of the RFLPFNN controller,

\[
y_o = U^{RFLPFNN}(t) \]

can be rewritten as

\[
U^{RFLPFNN} = W^{RFLPFNN} (E, \Theta, \mu, \sigma) = \Theta^T \Omega
\]

where the tracking error vector \( E \) is the input of the RFLPFNN, \( \Theta \) are the collections of the adjustable parameters \( (\omega_{M}, \beta^i_k, \sigma^i_k) \), \( \Omega \) is the output vector \( (\psi_k, \Phi_m) \) and \( E = [e^{m}_{\Theta} e^{m}_{\mu}]^T \) is the tracking error input vector to the RFLPFNN controller.

3.3 Learning Algorithms of the Recurrent FLNN-based PFNN Model

This section presents the online learning algorithm for constructing the recurrent FLNN-based PFNN model. The proposed learning algorithm comprises structure learning and a parameter learning algorithms. Structure learning is based on the entropy measure used to determine whether a new rule should be added to satisfy the fuzzy partitioning of input variables [52]. Parameter learning is based on supervised learning algorithms. The backpropagation algorithm minimizes a given cost function by adjusting the link weights in the consequent part and the parameters of the membership functions [46]. Initially, there are no nodes in the network except the input-output nodes, i.e., there are no nodes in the RFLPFNN model. The nodes are created automatically as learning proceeds, upon the reception of online incoming training data in the structure and parameter learning processes.

3.4 Robust Control Design and Stability Analysis of the IACS

In this section, the intelligent adaptive control system is proposed to mimic the optimal control law defined in (14) using RFLPFNN controller and the robust controller is designed with adaptive bound estimation algorithm to compensate the difference between the optimal control law and the output of the RFLPFNN controller. The proposed controller combines the merits of the PFNN [45], recurrent neural network and FLNN. The design of robust controller is necessary to compensate the minimum approximation error instead of increasing the rules of the RFLPFNN controller. From (11), (12) and (14), an error equation is obtained as follows:

\[
\dot{E} = \Lambda E + \bar{B}_m \left( U^{*} - U^{RFLPFNN} - U^{BC} \right)
\]

where \( \Lambda = \begin{bmatrix} 0 & 1 \\ -k_2 & -k_1 \end{bmatrix} \) is a stable matrix and \( \bar{B}_m = [0 \quad B_m]^T \). To develop the robust controller, a minimum approximation error \( \epsilon \) is defined as:

\[
\epsilon = U^{*} - U^{RFLPFNN} (E, \Theta^*, \mu^*, \sigma^*)
\]
where $\Theta^*$ is the optimal weight vector achieves the minimum approximation error and $\varepsilon$ is the approximation error and is assumed to be bounded by $|\varepsilon|<\delta$. $\Theta$, $\mu$, and $\sigma$ are the optimal parameters of $\Theta$, $\mu$ and $\sigma$ in the RFLPFNNC. From (32), the error equation in (31) can be rewritten as:

$$E = \Lambda E + B_m(U_q - U_{RFLPNNC})$$

$$= \Lambda E + B_m(U_q - U_{RFLPNNC})$$

$$+ [U_{RFLPNNC} - U_{RC}] - U_{RC}$$

(33)

where $\tilde{\Theta} = (\Theta^* - \Theta)$ and $\tilde{\Omega} = (\Omega^* - \Omega)$. The weights of the RFLPFNNC are updated online to guarantee the closed-loop stability and perfect tracking performance. To achieve this goal, the linearization technique is used to transform the nonlinear output of PRFLPFNCC into partially linear form so that the Lyapunov theorem extension can be applied. The expansion of $\tilde{\Omega}$ in Taylor series is obtained as:

$$\tilde{\Omega} = \frac{\partial \Omega}{\partial \mu} \tilde{\mu} + \frac{\partial \Omega}{\partial \sigma} \tilde{\sigma} + O_U$$

where $\Omega_\mu = \left[\left(\frac{\partial \Omega_1}{\partial \mu}\right) \quad \left(\frac{\partial \Omega_2}{\partial \mu}\right) \quad \left(\frac{\partial \Omega_3}{\partial \mu}\right)\right]_{\mu=\tilde{\mu}}$, $\Omega_\sigma = \left[\left(\frac{\partial \Omega_1}{\partial \sigma}\right) \quad \left(\frac{\partial \Omega_2}{\partial \sigma}\right) \quad \left(\frac{\partial \Omega_3}{\partial \sigma}\right)\right]_{\sigma=\tilde{\sigma}}$, $\tilde{\mu} = (\mu^* - \mu)$, $\tilde{\sigma} = (\sigma^* - \sigma)$ and $O_U$ is a vector of higher order terms and assumed to be bounded by a positive constant. Rewriting (34), we can obtain that

$$\Omega^* = \Delta + \Delta^* \tilde{\mu} + \Delta^* \tilde{\sigma} + O_U$$

(35)

Assume that $\tilde{U}_q = (U_q - U_q)$

(36)

From (35) and (36), we can obtain

$$\tilde{U}_q = (U_q - U_q)$$

$$= \frac{\partial \Omega}{\partial \mu} \tilde{\mu} + \frac{\partial \Omega}{\partial \sigma} \tilde{\sigma} + O_U$$

(37)

where the uncertain term $\Gamma = \frac{\partial \Omega}{\partial \mu} \tilde{\mu} + \frac{\partial \Omega}{\partial \sigma} \tilde{\sigma}$ is assumed to be bounded (i.e. $|\Gamma|<\rho$). According to (33) and (35)-(37), the error dynamics can be represented as

$$\dot{E} = \Lambda E + \bar{B}_m(\varepsilon + \tilde{U}_q - U_{RC})$$

$$= \Lambda E + \bar{B}_m(\tilde{\Theta}^T \tilde{\Omega} + \tilde{\Theta}^T \Omega^* \tilde{\mu} + \tilde{\Theta}^T \Omega^* \tilde{\sigma} + \varepsilon + \Gamma - U_{RC})$$

(38)

**Theorem:** Consider the IM servo drive system represented by (11), if the intelligent controller is designed as (12), in which the adaptation laws of the RFLPFNNN controller are designed as (39)-(41) and the robust controller is designed as (42) with the adaptive bound estimation algorithms given in (43) and (44). As a result, the stability of the intelligent adaptive control system can be guaranteed.

$$\dot{\Theta} = \eta_\Theta E^T P B_m \tilde{\Theta}$$

$$\dot{\mu} = \eta_\mu E^T P B_m \tilde{\Theta}$$

$$\dot{\sigma} = \eta_\sigma E^T P B_m \tilde{\Theta}$$

$$\dot{U}_{RC} = (\tilde{\Theta} + \tilde{\rho}) \text{sgn}(E^T P B_m)$$

(40)

$$\dot{\delta}(t) = \eta_\delta E^T P B_m$$

$$\dot{\rho}(t) = \eta_\rho E^T P B_m$$

(41)

(42)

(43)

(44)

where $\eta_\Theta, \eta_\mu, \eta_\sigma, \eta_\delta$ and $\eta_\rho$ are strictly positive learning rates, sgn() is the sign function, $\delta(t)$ and $\rho(t)$ are the on-line estimated values of the adaptive bounds $\delta(t)$ and $\rho(t)$.

**Proof:** To minimize the error function and to derive the adaptation laws of $\Theta$, $\mu$, $\sigma$, $\delta$ and $\rho$ for the intelligent adaptive control system, a Lyapunov function is defined as:

$$V(E, \tilde{\Theta}, \tilde{\mu}, \tilde{\sigma}, \tilde{\Theta}, \tilde{\rho}, t)$$

$$= \frac{1}{2} E^T P E + \frac{1}{2} \tilde{\Theta}^T \tilde{\Theta} + \frac{1}{2} \tilde{\Theta}^T \tilde{\Theta}$$

$$\geq \frac{1}{2} \tilde{\Theta}^T \tilde{\Theta} + \frac{1}{2} \tilde{\Theta}^T \tilde{\Theta}$$

where $\tilde{\delta} = (\tilde{\delta} - \delta)$ and $\tilde{\rho} = (\tilde{\rho} - \rho$) are the estimated errors and $P \in \mathbb{R}^{n \times n}$ is a symmetric positive-definite matrix, which satisfies the following Lyapunov equation [53], [54].

$$A^T P + PA = -Q$$

(45)

where $Q \in \mathbb{R}^{n \times n}$ is a given symmetric positive definite matrix, $Q > 0$. By taking the derivative of the Lyapunov function (45) and using (38) and (46), it is obtained that:

$$V(E, \tilde{\Theta}, \tilde{\mu}, \tilde{\sigma}, \tilde{\Theta}, \tilde{\rho}, t)$$

$$= \frac{1}{2} E^T P E + \frac{1}{2} \tilde{\Theta}^T \tilde{\Theta} + \frac{1}{2} \tilde{\Theta}^T \tilde{\Theta}$$

$$\geq \frac{1}{2} \tilde{\Theta}^T \tilde{\Theta} + \frac{1}{2} \tilde{\Theta}^T \tilde{\Theta}$$

(46)

(47)

Substitute (38)-(44) into (47), then
4 Numerical Simulation and Experimental Results

In order to investigate the effectiveness of the proposed tracking control scheme, the simulation and experimentation of the proposed IACS are carried out using MATLAB/SIMULINK package based on the control system shown in Figs. 1 and 3. The simulation and experimental results of the IM servo drive system are presented to verify the feasibility of the proposed IACS under various operating conditions. The threshold values, learning rates and the gains of the proposed control scheme are given as follows: \( D = 0.35 \), \( d_m = 0.25 \), \( \eta_0 = 0.75 \), \( \eta_p = 0.004 \), \( \eta_p = 0.005 \), \( \eta_p = 0.003 \), \( \eta_p = 0.3 \). All the proposed threshold values, learning rates and control gains in the IACS are chosen to achieve the superior transient control performance in the simulation and experimentation considering the limitation of control effort, the requirement of stability and the possible operating conditions. When the threshold value \( d_m = 0 \) is set, the performance of the PFNN control system is the same as the one of the FNN control system because all the control rules in the network structure are fired at this situation. Although the computational time can be gradually decreased by increasing the threshold value, the control performance also deteriorates little by little. Therefore, we have to compromise between the control performance and computational complexity. The control performance in the dynamic threshold value of the RFLPFNN can be approximately determined as \( \gamma = 0.35 \) and \( \xi = 250 \).

4.1 Numerical Simulation of the IM Servo Drive System

All numerical simulations are carried out using Matlab/Simulink package. The control objective is to control the position of the IM servo drive system to track the reference model trajectory. To investigate the effectiveness and robustness of the proposed control system, four simulated conditions including parameter uncertainties (PU) and external load disturbance are considered. The mechanical time constant of the IM is given by \( \tau_m = (\beta_m / J_m) \).

Case 1: \( 1.0 \times \tau_c , 1.0 \times \tau_m , T_i = 0-12 \) N.m
Case 2: \( 0.5 \times \tau_c , 0.5 \times \tau_m , T_i = 0-12 \) N.m
Case 3: \( 1.5 \times \tau_c , 2.5 \times \tau_m , T_i = 0-12 \) N.m
Case 4: \( 1.5 \times \tau_c , 5.0 \times \tau_m , T_i = 0-12 \) N.m

The dynamic performance of the IM servo drive due to reference model command under subsequent loading of 12 N.m for the PFNN controller alone at Case (1) of PU including the responses of the reference model and rotor position, the tracking
position error, rotor speed, the tracking speed error, d-q axis current response and adaptive signals are predicted in Fig. 4(a), respectively. On the other hand, the dynamic performance of the IM servo drive using the IACS using RFLPFNN and robust controllers is shown in Fig. 4(b) at Case (1) of PU. The disturbance rejection capabilities have been checked when a load of 12 N.m is applied to the shaft at $t = 2.5$ sec and removed at $t = 7.5$ sec. The results obtained in Fig. 4 illustrate good dynamic performances, in command tracking and load regulation performance, are realized for both position tracking controllers. Improvement of the control performance by addition the proposed IACS can be observed from the obtained results in command tracking and load regulation characteristics. From these results shown in Fig. 4, the tracking position error and tracking speed error with the PFNN controller is larger than the ones using the IACS.
Fig. 4 Dynamic response of the IM servo drive system for the reference position and subsequent loading of 12 N.m for both position controllers at Case (1) of parameter uncertainties.

(a) Using PFNN tracking controller  
(b) Using IACS with RFLPFNN tracking controller
Fig. 4 (Continued) Dynamic response of the IM servo drive system for the reference position and subsequent loading of 12 N.m for both position controllers at Case (1) of parameter uncertainties. (a) Using PFNN tracking controller (b) Using IACS with RFLPFNN tracking controller

To further verify the performance robustness of the proposed control schemes, four cases of PU and external load disturbance are considered, Cases (1~4), for comparison. The dynamic performance of the IM servo drive for both position controllers at all Cases of PU is predicted in Fig. 5. From the simulation results shown in Fig. 5(b), the tracking errors converge quickly and the robust control characteristics of the IM servo drive system using the proposed IACS under the occurrence of PU can be clearly observed. The proposed IACS provides a rapid and accurate response for the reference model under load changes within 0.5 sec compared with the PFNN position tracking controller which has sluggish recovery time of more than 1.0 sec at PU as shown in Fig. 5(a). Furthermore, the maximum tracking position errors at four cases of PU are approximately ±0.6 rad, for the PFNN controller. On the other hand, the ones with the IACS at four examined cases of PU are approximately constants and equal ±0.25 rad. Comparing the IACS with the PFNN controller, the tracking errors and regulation characteristics using IACS are much reduced. Therefore, the proposed IACS with RFLPFNN can yield superior control performance than the PFNN controller. As a result, the proposed IACS provides a rapid and accurate response for the reference model under load changes compared with the PFNN position tracking controller which has sluggish recovery time. Perfect tracking response and robust characteristics can still be kept with regard to PU and external disturbances as shown in Fig. 5(b). Thus, it can be verified that the proposed IACS at all cases of PU can satisfy the robustness, the accuracy requirements and is more suitable in the tracking control of the IM drive for industrial applications.

4.2 Experimentation of the IM Servo Drive System

The experimental setup for the IM servo drive system is shown in Fig. 3. A DSP control board dSPACE DS1102, which is based on a TMS320C31 and TMS320P14 DSPs, is installed in the control computer which includes multi-channels of ADC, DAC, PIO and encoder interface circuits. Digital filter and frequency multiplied by four circuits are built into the encoder interface circuits to increase the precision of the position feedback signal and coordinate transformations. The sampling rate is chosen as 200μs and hence, the carrier frequency of the PWM inverter is 5 kHz. The control interval of the position control loop is set at 1 ms. The current-regulated PWM VSI is implemented using MITSUBISHI intelligent power module (IPM) using...
IGBT components with a switching frequency of 15 kHz and driven by a six SEMIKRON IGBT drivers. The DC-link LC filter components are an inductor of iron powder core with 250µH and a polypropylene-film capacitor with 5µF. The position acquisition has been performed with a 5000 pulses/revolution incremental optical encoder. Therefore, the output of the frequency multiplier circuit is 4×5000 pulses/revolution which results high precision of the speed/position measurement.
Comparing the IACS with the PFNN controller, the tracking errors and regulation characteristics are much reduced using the proposed IACS. Therefore, the proposed IACS can yield superior control performance than the PFNN control scheme. As a result, the proposed IACS provides a rapid and accurate response for the reference model under load changes compared with the PFNN position tracking controller which has sluggish recovery time.

Fig. 6 Experimental results of the dynamic response of the IM servo drive for the reference position and subsequent loading of 12 N.m for both position controllers: position response 4 rad/div, speed response 7.5 (rad/sec)/div, tracking position error 0.3 rad/div, tracking speed error 3 (rad/sec)/div, q-d axis current response 4 A/div, adaptive position signal 2.5 rad/div, adaptive speed signal 10 (rad/sec)/div, time base for all traces 1 sec/div. at Case (1) of PU
(a) Using PFNN tracking controller (b) Using IACS with RFLPFNN tracking controller
To further verify the performance of the proposed control schemes applied to the IM servo drive in practical applications, some experimental results are provided here. The experimental results of the dynamic performance for the proposed PFNN controller due to reference model command under subsequent loading of 12 N.m at Case (1) of PU including the responses of the reference model and rotor position, the tracking position error, rotor speed, the tracking speed error, d-q axis current response and adaptive control signals are predicted in Fig. 6(a), respectively. On the other hand, the experimental results of the IM servo drive using the proposed IACS is shown in Fig. 6(b) at the same conditions. Furthermore, the disturbance rejection capabilities have been checked for both position controllers. The experimental results obtained in Fig. 6 clearly illustrate good dynamic performances, in command tracking and load regulation performance, are realized for both position tracking controllers. Comparing the IACS with the PFNN controller, the tracking errors and regulation characteristics are much reduced using the proposed IACS. Therefore, the proposed IACS can yield superior control performance than the PFNN control scheme. As a result, the proposed IACS provides a rapid and accurate response for the reference model under load changes compared with the PFNN position tracking controller which has sluggish recovery time.

4.3 Performance Measures of the IM Servo Drive System

To measure the performance of the IM servo drive system, the maximum tracking error, $TE_{max}$, the average tracking error, $TE_{mean}$ and the standard deviation of the tracking error, $T_{sd}$, are defined as follows [2]:

$$TE_{max} = \max_k \sqrt{T(k)^2}$$  \hspace{1cm} (52)

$$TE_{mean} = \frac{\sum_{k=1}^{n} T(k)}{n}$$ \hspace{1cm} (53)

$$T_{sd} = \sqrt{\frac{\sum_{k=1}^{n} (T(k) - T_{mean})^2}{n}}$$ \hspace{1cm} (54)

where $T(k) = [\theta^m(k) - \theta_r(k)]$.

The performance measures can be easily demonstrated using the $TE_{max}$ and the $TE_{mean}$. Moreover, the oscillation of the position tracking error can be measured using $T_{sd}$. To further investigate the improvement of the proposed IACS, the performance measures of the 2DOF I-PDC, PFNNC and IACS with RFLPFNN at the four cases of PU are compared and given in Fig. 7. The same
performance measures are compared and in Tables (2, 3 and 4) for simulation. From these results, one can easily observe that all values of $TE_{\text{max}}$, $TE_{\text{mean}}$ and $TE_{\text{sd}}$ have been successfully reduced by the proposed IACS with RFLPFNN. Therefore, the IACS possesses the best robust control characteristics and can control the IM servo drive system effectively.

**5 Conclusion**

This paper proposed an IACS using RFLPFNN for IFOC-IM servo drive which guarantees the robustness in the presence of parameter uncertainties and load disturbances. The proposed IACS comprises a RFLPFNN controller and a robust controller. The RFLPFNN combines the merits of the PFNN, RFNN and FLNN. The RFLPFNN controller uses the FLNN to the consequent part of the fuzzy rules. The RFLPFNN model can automatically construct and adjust free parameters by performing online structure/parameter learning schemes concurrently. In the proposed control scheme, the RFLPFNN controller is used as the main tracking controller to mimic an optimal control law and the robust controller is designed to compensate the difference between the optimal control law and the RFLPFNN controller. Moreover, an on-line parameter training methodology, which is derived based on the Lyapunov stability analysis and the back propagation method, is proposed to guarantee the asymptotic stability of the IACS for IM servo drive system and to increase the learning of the RFLPFNN. To relax the requirement for the bound of minimum approximation error, optimal parameter vector and higher order term in Taylor series, an adaptive control law is utilized to estimate these bounds. The theoretical bases of the proposed control scheme are derived in details. The simulated and experimental results due to reference model trajectory confirm that the proposed IACS grants robust performance and precise dynamic response regardless of load disturbances and IM parameter uncertainties. Finally, the main contribution of this paper is the successful
development, application and implementation of the IACS with RFLPFN and robust controller methodology to control the rotor position of the IM considering the existence of load disturbances and parameters uncertainties.
