Abstract:- A constructive algorithm to implement convex recursive deletion regions via two-layer perceptrons has been presented in a recent study. In the algorithm, the absolute values of the weights become larger and larger when the number of nested layers of a convex recursive deletion region increases. In addition, the absolute values of the weights are determined according to the complexity of the structure of the convex recursive deletion region. More complicated convex recursive deletion regions result in larger values of weights. Besides, the constructive procedure is needed to get the parameters (weights and thresholds) for the neural networks. In this paper, we propose a simple three-layer network structure to implement the convex recursive deletion regions in which all weights of the second and third layers are all 1's and the thresholds for the nodes in the second layer are pre-determined according to the structures of the convex recursive deletion regions. This paper also provides the activation function for the output node. In brief, all of parameters (weights and activation functions) in the proposed structure are pre-determined and no constructive algorithm is needed for solving the convex recursive deletion region problems. We prove the feasibility of the proposed structure and give an illustrative example to demonstrate how the proposed structure implements the convex recursive deletion regions. Finally, we provide the conceptual diagram of the hardware implementation of the proposed network structure.

Key-words:- Multi-layer perceptrons, nested decision region, convex recursive deletion region, hardware implementation.

1. Introduction

A multi-perceptron is a layered structure neural network where weights are used to connect the nodes between adjacent layers and to perform necessary computations to implement classification problems. Training algorithms are used to train the weights and get the desired mappings from inputs to outputs. However, using training algorithm to optimize the weight spends a lot of computational time. Some studies focused on the partitioning capabilities of multi-layer perceptrons [1-9]. It has been known that the first layer of a multi-layer perceptron produces decision boundaries for classifications and the rest of layers implement the mappings from the inputs to the outputs [1]. It has been known that single-layer percetrons can determine linearly separable decision regions, two-layer perceptrons can partition either convex open or closed decision regions, and three-layer perceptrons are capable of implementing of any shapes of decision regions [2]. Recent research also indicated that convex recursive deletion regions can be implemented by two-layer perceptrons [3]. A general study on the partitioning capabilities of two-layer perceptrons can be found in [4] where the authors presented the Weight Deletion/Selection Algorithm to examine the feasibility of implementation of decision regions. A constructive algorithm to implement convex recursive deletion regions has been presented in [5]. The space partitioning multi-layer perceptron model has been proposed to solve some intractable classification problems [6]. A new two-layer paradigm with bithreshold and the increment of the dimensionality of the output of the first layer has been proposed and shown to be capable of implementing arbitrary decision regions in input space [7]. The partitioning capability of single-hidden layer feedforward neural networks with any continuous bounded non-constant activation function or any arbitrary bounded activation function has been discussed in [8]. A constraint based decomposition training architecture for a multi-layer perceptron has been proposed where the second layer and third layer of a three-layer perceptron function as logic "AND" and "OR",

respectively [9].

The convex recursive deletion regions have been solved by the two-layer perceptrons where a constructive algorithm is used to determine the weights and the threshold for the two-layer perceptrons [5]. However, the absolute values of the weights determined by the constructive algorithm become larger and larger when the number of nested layers of a convex recursive deletion region increases. The absolute values of the weights also depend on the complexity of the structure of the convex recursive deletion region. If the structure of the convex recursive deletion region is very complicated, the absolute values of the weights determined by the constructive algorithm could be very large. This might probably cause computational overflowing problems for integer manipulations. Besides, we still need to use the constructive procedure to get the parameters (weights and thresholds) for the neural networks. In this paper, we propose a simple three-layer network structure to implement the convex recursive deletion regions in which all weights of the second and third layers are all 1's and the thresholds for the nodes in the second layer are pre-determined according to the structures of the convex recursive deletion regions. We also provide the activation function for the output node. In brief, all of parameters (weights and activation functions) in the proposed structure are pre-determined and no constructive algorithm is needed for solving the convex recursive deletion region problems. We also prove the feasibility of the proposed structure and give an illustrative example to demonstrate how the proposed structure implements the convex recursive deletion regions. Finally, we provide the conceptual diagram of the hardware implementation of the proposed network structure.

For the visual reason, in this paper, we use two-dimensional examples to explain how a multi-layer perceptron forms the decision boundaries, and how the proposed network structure implements the convex recursive deletion regions.

2. Preliminaries

2.1 Forming of Decision Regions

To explain how the first layer of a multi-layer perceptron forms decision boundaries, we present a two-class classification example implemented by a two-layer perceptron. This example is taken from [1,4] and shown in Figure 1. Figure 1(a) is a two-layer perceptron with two inputs, four nodes in the first layer (the hidden layer) and one node in the second layer (the output layer). Figure 1(b) is the corresponding decision region where the two inputs generate a two-dimensional input space which is linearly divided into 11 sub-regions (numbered from 1 to 11) by four partitioning lines. The shaded sub-regions belong to class A, while the blank ones belong to class B.

It is important to know that each node in the first layer will form a two-dimensional partitioning line in the corresponding decision region because it is a linear combination of inputs x_1 and x_2. To implement the four partitioning lines, one therefore needs four nodes in the first layer with one-to-one corresponding relationship to the four partitioning lines. For convenience, we use the same labels (z_1 to z_4) to represent the four nodes and their associated partitioning lines. Each node in the first layer produces a "1" output if the input is on one side of its corresponding partitioning line, and a '0' output if on the other side. The second layer performs the mappings from the first layer to the second layer and makes a final decision. It is important to note that the weights in the first layer are pre-determined if a decision region is established. To implement the decision regions using two-layer perceptrons, one only needs to get the weights of the second layer of the two-layer perceptrons.

In Figure 1, the first layer partitions the input space into 11 sub-regions. The second layer serves to classify these sub-regions into the two classes (class A and class B). The θ value for a sub-region is defined as follows

$$\theta_l = \sum_{k=1}^{r} w_k z_k \tag{1}$$

where θ_l is the θ value of sub-region l, r is the number of partitioning lines in the decision region, and w_k is the weight connecting first layer node z_k with the output node.

The two-class classification problem is implemented by the following activation function (hard limiter):

$$y = \begin{cases} 1 \ (\text{class A}) & \text{if} \quad \theta_l \geq \theta_h \\ 0 \ (\text{class B}) & \text{if} \quad \theta_l < \theta_h \end{cases} \tag{2}$$

where θ_h is the threshold for the second layer node.

It has been known that the necessary and sufficient condition for implementing two-class classification problems in a decision region is the minimum θ value of sub-regions belonging to class A must be greater than the maximum θ value of sub-regions belonging to class B.

2.2 Convex Recursive Deletion Region

Consider an n-dimensional Euclidean space $\boldsymbol{R}^n$. Let C_0 be the input space in $\boldsymbol{R}^n$, and C_1, C_2… , C_p be a series of nested convex polyhedrons with the following relation:

$$C_0 \supset C_1 \supset C_2 \supset \cdots \supset C_p \quad (3)$$

A *convex recursive deletion region S* is a set of the form [5]:

$$S = (C_0 \cap \overline{C}_1) \cup (C_2 \cap \overline{C}_3) \cup \cdots \cup (C_{p-1} \cap \overline{C}_p) \quad (4)$$

where $\overline{C}_i$ denotes the complement of C_i.

Figure 2 shows the example of a convex recursive deletion region consisting of three nested convex polyhedrons: C_1, C_2, and C_3. Each of the three convex polyhedrons is bounded by a group of hyper-planes. We call the hyper-planes bounding a convex polyhedron ***"bounding hyper-planes"*** of the convex polyhedron. For example, in Figure 2 (b), C_1 is bounded by bounding hyper-planes z_1, z_2, z_3, z_4, and z_5. C_2 is bounded by bounding hyper-planes z_6, z_7, and z_8. C_3 is bounded by bounding hyper-planes z_9, z_{10}, z_{11}, and z_{12}. A bounding hyper-plane divides the space into two linearly separable hyper-planes. The '1' side of a bounding hyper-plane of a convex polyhedron is the separable hyper-plane toward the convex polyhedron, and the '0' side is the other one. The '1' sides and '0' sides of the bounding hyper-planes for C_1, C_2, and C_3 are shown in Figure 2 (b).

A pattern is in a convex polyhedron if and only if it is on the '1' sides of *all* bounding hyper-planes of the convex polyhedron. We can set up a threshold in each node in the second layer associated with a particular convex polyhedron to be the number of the bounding hyper-planes of the convex polyhedron, and therefore determine whether the pattern is in the convex polyhedron or not.

3. The Proposed Network Structure and Hardware Implementation

3.1 Neural Network Structure

The proposed neural network is a three-layer structured network. Figure 3 shows the example of the proposed network. The first layer of the network serves to form a convex recursive deletion region. The second layer detects the pattern location in the convex recursive deletion region. The third layer determines whether the pattern belongs to class A or class B according to the pattern location detected by the second layer. All of the weights in the second and three layers are set to be 1's. The threshold for a node in the second layer (θ_h) associated with a particular convex polyhedron is equal to the number of the bounding hyper-planes of the convex polyhedron. The output layer consists of only one node. Let $v = \sum_{t=1}^{q} C_t$ where C_t is a second layer node and q is the number of the second layer nodes. The activation function for the output node y is as follows:

$$y = \begin{cases} f(v) = (v+1) \bmod 2, \text{ if } C_0 \cap \overline{C}_1 \text{ belongs to class A} \\ f(v) = v \bmod 2, \quad \text{if } C_0 \cap \overline{C}_1 \text{ belongs to to class B} \end{cases} \quad (5)$$

where notation 'mod' denotes a modulus (remainder) operation of two integer numbers.

3.2 Proof of The Network Structure

The proof is straightforward. We explain it by Figure 2 and Figure 3. In Figure 2, the convex recursive deletion region consists of three nested convex polyhedrons: C_1, C_2, and C_3. In this case, $C_0 \cap \overline{C}_1$ belongs to class B. If a pattern is in $C_0 \cap \overline{C}_1$, none of the nested convex polyhedrons contains the pattern. v is therefore equal to 0. By Eq. (5), y = 0 (class B). If a pattern is in $C_1 \cap \overline{C}_2$, only C_1 contains the pattern. v is equal to 1, and y = 1 (class A). If a pattern is in $C_2 \cap \overline{C}_3$, both C_1 and C_2 contain the pattern. v is equal to 2, and y = 0 (class B). If a pattern is in C_3, all of the three convex polyhedrons (C_1, C_2, and C_3) contain the pattern. v is equal to 3, and y = 1 (class A).

One can use the similar procedure to get the sequentially alternative classification results (0 and 1) for any convex recursive deletion regions.

Similarly, one can easily prove the feasibility of the proposed structure when $C_0 \cap \overline{C}_1$ belongs to class A.

Figure 3 is the neural network to implement the convex recursive deletion region shown in Figure 2. In Figure 3, all of the weights of the second and third layers are 1's. The thresholds for the nodes of the second layer and the activation function for the output node are also demonstrated in the figure.

3.3 Hardware Implementation

In the proposed network structure, the weights and activation functions are pre-determined and no constructive algorithm is needed for implementing the convex recursive deletion regions. Therefore, it is easily realized by hardware implementation. Figure

4 is the conceptual diagram of the hardware implementation of the proposed network structure. In Figure 4, the multiplier and adder of the first layer serve to form the decision boundaries (the linear combinations of the inputs). Each of the comparators in the figure serves as an activation function (hard limier). The weights of the second layer are all 1's. We only need an adder and a comparator to perform the functionality of the second layer. The activation function of the third layer is the modulus operation dividing the input of the activation function by 2. The output of the activation function will be sequentially alternative (0 or 1) when the input of the activation function increases (0, 1, 2, 3, 4, …). This is realized by taking the least significant bit of the input of the activation function. Therefore we use an adder and take its least significant bit to perform the functionality of the third layer.

4. Conclusions

We proposed a simple three-layer network structure to implement the convex recursive deletion regions in which all parameters (weights and activation functions) are pre-determined according to the structures of the convex recursive deletion regions. No constructive algorithm is needed for solving the convex recursive deletion region problems. We used an illustrative example to explain how the first layer of a multi-layer perceptron forms the decision boundaries. We also proved the feasibility of the network structure, and provided the conceptual diagram of the hardware implementation of the proposed network structure.
