# A Novel Boolean Algebraic Framework for Association and Pattern Mining 

Hatim A. Aboalsamh<br>Department of Computer Sciences<br>King Saud University<br>P.O. Box 2454 Riyadh 11451<br>Saudi Arabia<br>Hatim@ccis.ksu.edu.sa<br>http://faculty.ksu.edu.sa/Aboalsamh/

#### Abstract

Data mining has been defined as the non- trivial extraction of implicit, previously unknown and potentially useful information from data. Association mining and sequential mining analysis are considered as crucial components of strategic control over a broad variety of disciplines in business, science and engineering. Association mining is one of the important sub-fields in data mining, where rules that imply certain association relationships among a set of items in a transaction database are discovered. In Sequence mining, data are represented as sequences of events, where order of those events is important. Finding patterns in sequences is valuable for predicting future events. In many applications such as the WEB applications, stock market, and genetic analysis, finding patterns in a sequence of elements or events, helps in predicting what could be the next event or element. At the conceptual level, association mining and sequence mining are two similar processes but using different representations of data. In association mining, items are distinct and the order of items in a transaction is not important. While in sequential pattern mining, the order of elements (events) in transactions (sequences) is important, and the same event may occur more than once. In this paper, we propose a new mapping function that maps event sequences into itemsets. Based on the unified representation of the association mining and the sequential pattern, a new approach that uses the Boolean representation of input database D to build a Boolean matrix M . Boolean algebra operations are applied on M to generate all frequent itemsets. Finally, frequent items or frequent sequential patterns are represented by logical expressions that could be minimized by using a suitable logical function minimization technique.

Keywords:- Sequence mining, data mining, association mining, Boolean association expressions, Boolean matrix, Association matrix.

## 1 Introduction

Data mining is the process of discovering potentially valuable patterns, associations, trends, sequences and dependencies in data $[2,3,4,5,11,17,25,16,14]$. Key business examples include web site access analysis for improvements in e-commerce advertising, fraud detection, screening and investigation, retail site or product analysis, and customer segmentation. Data mining techniques can discover information that many traditional business analysis and statistical techniques fail to deliver. Additionally, the application of data mining techniques further exploits the value of data
warehouse by converting expensive volumes of data into valuable assets for future tactical and strategic business development. Management information systems should provide advanced capabilities that give the user the power to ask more sophisticated and pertinent questions. It empowers the right people by providing the specific information they need.
Association mining and sequence mining are two of the central tasks in data mining. Association mining is the process of producing association rules to express positive connections between items $2,3,4,5,6,18,21$, $29,9,20]$, while sequence mining is the task of
discovering frequent patterns among a large sequence database $[1,7,8,10,11,12,15,23,26,27,14,33]$. There is a connection between the two tasks in the way of extracting knowledge. The two tasks are related in the way they are handled. The Apriori algorithm [2] has been conceptually used in handling the two tasks.
The framework we develop derives from the observation that association mining and sequence mining are two similar processes on different representations of transactions. In association mining, the order of items in a transaction is not important, and all elements are distinct. While, in sequential pattern mining, the order of elements (events) in the transaction (sequence) record is important, and the same event may occur more than once. So, first we need to define a mapping function that maps a sequence of elements, which are ordered and could be repeated, into a set of elements, where ordering is not important, and elements are distinct.
In this paper, we propose a new mapping function that maps event sequence into events set. Based on the unified representation of the association mining and the sequential pattern, a new approach that uses the Boolean representation of the input database D is introduced. Database D is scanned only once to build a Boolean matrix $\mathrm{M} . \mathrm{M}$ has n columns and k rows, where N is the number of items in $i$, and $k$ is the number of transactions in D. A position ( $\mathrm{i}, \mathrm{j}$ ) in M is 1 iff in transaction I , item j exists, and 0 otherwise. Boolean algebra operations are applied on M to generate all frequent itemsets. Finally, frequent items or frequent sequential patterns are represented by a logical expression that could be minimized by using a suitable logical function minimization technique. The Boolean approach does not depend on a specific association mining technique. In this paper, we use the apriori like algorithm for demonstrating the Boolean mining approach.
The rest of this paper is organized as follows: In section 2 , we give the problem definition. The sequential pattern mapping is given in section 3. In section 4, the Boolean approach is presented. The frequent logical expressions are described in section 5 . The performance study is given in section 6. Finally, the paper is concluded in section 7.

## 2 Problem Definition

### 2.1 Notation

I Set of all items $\left\{i_{1}, i_{2}, \ldots, i_{n}\right\}$
$2^{1} \quad$ Set of all possible transactions.
T A transaction
t An element in T, $\mathrm{t} \in \mathrm{T}$
$\mathrm{D}_{\mathrm{T}} \quad$ Set of transactions $\left\{\mathrm{T}_{1}, \mathrm{~T}_{2}, \ldots, \mathrm{~T}_{\mathrm{k}}\right\}$
S A sequence
s an element in $S$
$D_{s} \quad$ Set of sequences $\left\{S_{1}, S_{2}, \ldots, S_{k}\right\}$
$P(T)$ A mapping function that maps $T$ into a sequence $S$
$\mathrm{Q}(\mathrm{S})$ A mapping function that maps S into a transaction T
$\|x\| \quad$ Number of 1 's in vector $x$

### 2.2 Association Mining

Association mining that discovers dependencies among values of an attribute was first introduced by Agrawal et al.[2] and has emerged as a prominent research area. The association mining problem also referred to as the market basket problem can be formally defined as follows. Let $I=\left\{i_{1}, i_{2}, \ldots, i_{n}\right\}$ be a set of items as $S=$ $\left\{s_{1}, s_{2}, \ldots, s_{m}\right\}$ be a set of transactions, where each transaction $s_{i} \in S$ is a set of items that is $s_{i} \subseteq I$. An association rule denoted by $X \Rightarrow Y$, where $X, Y \subset I$ and $X \cap Y=\Phi$, describes the existence of a relationship between the two itemsets $X$ and $Y$.

### 2.3 Sequence Mining

Sequential patterns mining $[1,8,10,11,17,22,25,27$, $28,16,9]$ is the process of finding frequent sequential patterns in large transaction databases. It can be defined as followed. Let $\mathrm{I}=\left\{\mathrm{i}_{1}, \mathrm{i}_{2}, \ldots, \mathrm{i}_{\mathrm{n}}\right\}$ be a set of distinct items, and $S=e_{1}, e_{2}, \ldots, e_{m}$ be an ordered sequence of events, where $\forall e_{i} \epsilon S, 1 \leq i \leq m, e_{i} \epsilon I$. In a sequence $S$, an event e may occur more than once, and the ordering of events in S is important, i.e., sequence AB in not the same as sequence BA. The number, 1 , of events in $S$ is called the length of sequence $S$, and $S$ is called an 1 sequence. As an example, $\mathrm{S}=\mathrm{BBBCCAD}$ is an 8 sequence of events. An event sequence $\mathrm{S}_{1}=i_{a_{1}}, i_{a_{2}}, \ldots$, $i_{a_{m}}$, is contained in an event sequence $S_{2}=i_{b_{1}}, i_{b_{2}}, \ldots$, $i_{b_{k}}, m \leq \mathrm{k}, \quad$ if $i_{a_{1}} \leq i_{b_{1}}, i_{a_{2}} \leq i_{b_{2}}, \ldots, i_{a_{m}} \leq i_{b_{m}}$. If an event sequence $S_{1}$ is contained in event sequence $S_{2}$,
$S_{1}$ is called an event subsequence of $S_{2}$, and $S_{2}$ is called an event super-sequence of $S_{1} . S_{1}$ is an event subsequence of $S_{1}$, and $S_{1}$ is an event super-sequence of $S_{1}$.

## 3 Sequential Pattern Mapping

Let $I=\left\{i_{1}, i_{2}, \ldots, i_{n}\right\}$ be a set of distinct events [30], and $S=e_{1}, e_{2}, \ldots, e_{m}$ be an ordered sequence of events, where $\forall e_{i} \epsilon S, 1 \leq i \leq m, e_{i} \epsilon I$. In a sequence S , the order of events is important and an event e could occur more than once.

Example 3.1: Let $\mathrm{I}=\{\mathrm{A}, \mathrm{B}, \mathrm{C}, \mathrm{D}\}$ be the set of all possible events in database D , where D is given in Table 1.

| ID | Sequence |
| :--- | :--- |
| 1 | ADCCABB |
| 2 | DCACC |
| 3 | BABCCA |
| 4 | DCAA |
| 5 | DACCC |

Table 1
In the above database D , the first transaction $\mathrm{T}_{1}$ contains each of the events $\mathrm{A}, \mathrm{B}$ and C twice, and sequence ' ADC ' in transaction 1 is not the same as sequences 'DCA' and 'DAC' in transactions 4 and 5, respectively. As a sequence representation, the two transactions 2 and 5 are not the same, while if we consider D as a database of sets of items (ignore the repeated events), transactions 2 and 5 are identical transactions.
To unify the two representations of sets and sequences, we map the sequences into sets by identifying sequence elements by their positions. For a sequence $\mathrm{S}=e_{1} e_{2}, \ldots$, $e_{m}$, each element $e_{j}, 1 \leq j \leq m$, could be one of the possible n elements in I. If all possible elements at position j are labeled by j , then instead of writing $\mathrm{S}=$ $i_{a_{1}}, i_{a_{2}}, \ldots, i_{a_{m}}, \mathrm{~S}$ could be written as $\mathrm{S}=i_{a_{1}, 1}, i_{a_{2}, 2}, \ldots$, $i_{a_{m}, m}$. In this case, event $i_{a_{j}}, 1 \leq j \leq m$, that has order j in sequence S , would have a label $j$ describing its position.

Example 3.2: For the database D given in example 3.1, the mapping function applied on sequence transactions $S$ produces the database $\mathrm{D}_{\mathrm{T}}$ given in Table 2.

In example 3.2, sequence transaction $S_{i}$ is mapped into item transaction $\mathrm{T}_{\mathrm{i}}$ by attaching element position j of elements in $\mathrm{S}_{\mathrm{i}}$ to be mapped into $\mathrm{T}_{\mathrm{i}}$.

| $I D$ | $S$ | $T$ |
| :--- | :--- | :--- |
| 1 | ADCCABB | $\mathrm{A}_{1} \mathrm{D}_{2} \mathrm{C}_{3} \mathrm{C}_{4} \mathrm{~A}_{5} \mathrm{~B}_{6} \mathrm{~B}_{7}$ |
| 2 | DCACC | $\mathrm{D}_{1} \mathrm{C}_{2} \mathrm{~A}_{3} \mathrm{C}_{4} \mathrm{C}_{5}$ |
| 3 | BABCCA | $\mathrm{B}_{1} \mathrm{~A}_{2} \mathrm{~B}_{3} \mathrm{C}_{4} \mathrm{C}_{5} \mathrm{~A}_{6}$ |
| 4 | DCAA | $\mathrm{D}_{1} \mathrm{C}_{2} \mathrm{~A}_{3} \mathrm{~A}_{4}$ |
| 5 | DACCC | $\mathrm{D}_{1} \mathrm{~A}_{2} \mathrm{C}_{3} \mathrm{C}_{4} \mathrm{C}_{5}$ |

Table 2
Definition 3.1: Let $I=\left\{i_{1}, i_{2}, \ldots, i_{n}\right\}$ be a set of distinct events, then for a sequence $S=e_{1}, e_{2}, \ldots, e_{m}$, the transaction mapping function $P$ applied on $S, P: S \rightarrow T$ is defined as

$$
\mathrm{P}(\mathrm{~S})=\left\{t_{i, j} \mid \exists e_{j} \epsilon S \wedge t_{i}=e_{j} \wedge t_{i, j}=t_{i}\right\}
$$

According to definition $3.1, t_{i, j}=t_{i}$ for all $1 \leq j \leq m$, and $t_{i}=t_{i, j}$ for all $1 \leq j \leq m$.

Lemma 3.1: The order of elements in $\mathrm{T}=\mathrm{P}(\mathrm{S})$, is not important.
Proof: Since each element $e_{j} \in S$ is mapped to element $t_{i, j} \in T$, where position j is preserved, if we change the order of elements in T , they are still identified by their positions.

Definition 3.2: Let $\mathrm{I}=\left\{\mathrm{i}_{1}, \mathrm{i}_{2}, \ldots, \mathrm{i}_{\mathrm{n}}\right\}$ be a set of distinct events, then for a transaction $\mathrm{T}=\left\{t_{i, j} \mid t_{i, j}=t_{i} 1 \leq i \leq\right.$ $\left.n, t_{i} \epsilon I\right\}$ of cardinality m and ordered according to j , the sequence mapping function Q applied on $\mathrm{T}, \mathrm{Q}: \mathrm{T} \rightarrow \mathrm{S}$ is defined as

$$
\mathrm{Q}(\mathrm{~T})=\mathrm{e}_{1}, \mathrm{e}_{2}, \ldots, \mathrm{e}_{\mathrm{m}}, \mathrm{e}_{\mathrm{j}}=\mathrm{t}_{\mathrm{i}, \mathrm{j}} \text { and } t_{i} \in I
$$

Definition 3.3: Let $\mathrm{I}=\left\{\mathrm{i}_{1}, \mathrm{i}_{2}, \ldots, \mathrm{i}_{\mathrm{n}}\right\}$ be a set of distinct events, then for a transaction $\mathrm{T}=\left\{t_{i, j} \mid t_{i, j}=t_{i} 1 \leq i \leq\right.$ $\left.n, t_{i} \epsilon I\right\}$ of cardinality m and ordered according to j , the mapping factor $m f$ of event $t_{i} ; m f\left(t_{i}\right)$ is defined as the mapping space for $t_{i} ;$ i.e., $\left\|t_{i, j}\right\|$

Example 3.3: For the database $D_{T}$ given in table 2, the mapping function applied on item transactions T's produces the database $\mathrm{D}_{\mathrm{s}}$ shown in table 3 .

| ID | T | Orderd T | S |
| :---: | :---: | :---: | :---: |
| 1 | $\begin{array}{lll} \mathrm{A}_{3} & \mathrm{D}_{4} & \mathrm{C}_{1} \\ \mathrm{C}_{5} & \mathrm{~A}_{2} & \mathrm{~B}_{7} \\ \mathrm{~B}_{6} \end{array}$ | $\mathrm{C}_{1} \mathrm{~A}_{2} \mathrm{~A}_{3} \mathrm{D}_{4} \mathrm{C}_{5} \mathrm{~B}_{6} \mathrm{~B}_{7}$ | CAADCBB |
| 2 | $\begin{aligned} & \mathrm{D}_{1} \mathrm{C}_{5} \mathrm{~A}_{4} \\ & \mathrm{C}_{3} \mathrm{C}_{2} \\ & \hline \end{aligned}$ | $\mathrm{D}_{1} \mathrm{C}_{2} \mathrm{C}_{3} \mathrm{~A}_{4} \mathrm{C}_{5}$ | DCCAC |
| 3 | $\begin{array}{ll} \mathrm{B}_{6} \mathrm{~A}_{1} & \mathrm{~B}_{5} \\ \mathrm{C}_{2} \mathrm{C}_{3} \mathrm{~A}_{4} \\ \hline \end{array}$ | $\mathrm{A}_{1} \mathrm{C}_{2} \mathrm{C}_{3} \mathrm{~A}_{4} \mathrm{~B}_{5} \mathrm{~B}_{6}$ | ACCABB |
| 4 | $\begin{array}{ll} \hline \mathrm{D}_{1} \mathrm{C}_{3} \mathrm{~A}_{2} \\ \mathrm{~A}_{4} \end{array}$ | $\mathrm{D}_{1} \mathrm{~A}_{2} \mathrm{C}_{3} \mathrm{~A}_{4}$ | DACA |
| 5 | $\mathrm{D}_{4} \mathrm{~A}_{5} \mathrm{C}_{3}$ | $\mathrm{C}_{1} \mathrm{C}_{2} \mathrm{C}_{3} \mathrm{D}_{4} \mathrm{~A}_{5}$ | CCCDA |

Table 3

## 4 The Boolean Approach

Given a set of items $I=\left\{i_{1}, i_{2}, \ldots, i_{n}\right\}$, a transaction t is defined as a set of items such that $t \in 2^{I}$, where $2^{I}=\{\varnothing$, $\left.\left\{i_{1}\right\},\left\{i_{2}\right\}, \ldots,\left\{i_{n}\right\},\left\{i_{1}, i_{2}\right\}, \ldots,\left\{i_{1}, i_{2}, \ldots, i_{n}\right\}\right\}$. Let $T \subseteq 2^{I}$ be a given set of transactions $\left\{T_{1}, T_{2}, \ldots, T_{k}\right\}$.

Definition 4.1: Let $\mathrm{D}_{\mathrm{T}}=\left\{T_{1}, T_{2}, \ldots ., T_{k}\right\}$ be the set of all transactions in database D , with $k$ is the number of such transactions. The Association Matrix $M\left(D_{T}\right)$ is a $K \times N$ Boolean matrix where each element $a_{i, j}, l \leq i \leq K, l \leq j$ $\leq N, N \leq n$, in $M\left(D_{T}\right)$ is defined as

$$
a_{i, j}= \begin{cases}1 & \text { if } t_{j} \in T_{i} \\ 0 & \text { other wise }\end{cases}
$$

Definition 4.2: Let $\mathrm{D}_{\mathrm{T}}=\left\{T_{l}, T_{2}, \ldots ., T_{k}\right\}$ be the set of all transaction in database D , with $K$ is the number of such transaction. For element $\mathrm{e}_{\mathrm{j}}, l \leq j \leq N$, Vector

$$
f_{j}=\left[\begin{array}{l}
a_{1, j} \\
a_{2, j} \\
\\
a_{K, j}
\end{array}\right]
$$

is called the projection vector of $\mathrm{e}_{\mathrm{j}}$, and

$$
\operatorname{support}\left(\mathrm{e}_{\mathrm{j}}\right)=\left\|f_{j}\right\|_{1}
$$

Lemma 4.1: For elements $e_{j}$ and $e_{k}$ with projection vectors $f_{j}$ and $f_{k}$,

$$
\operatorname{support}\left(\mathrm{e}_{\mathrm{j}}, \mathrm{e}_{\mathrm{k}}\right)=\left\|f_{j} \wedge f_{k}\right\| .
$$

Proof: Following the definition of Boolean operators, the proof of lemma 4.1 is straightforward.
By generalizing lemma 4.1, we get the following lemma.
Lemma 4.2: For elements $e_{1}, e_{2}, \ldots, e_{m}$, with projection vectors $f_{1}, f_{2}, \ldots, f_{m}$,

$$
\operatorname{support}\left(\mathrm{e}_{1}, \mathrm{e}_{2}, \ldots, \mathrm{e}_{\mathrm{m}}\right)=\left\|f_{1} \wedge f_{2} \wedge \ldots \wedge f_{m}\right\|
$$

Proof: By induction, for $\mathrm{m}=2$, support $\left(\mathrm{e}_{1}, \mathrm{e}_{2}\right)=\left\|f_{1} \wedge f_{2}\right\|$. suppose it is true for $\mathrm{m}=\mathrm{n}$,

$$
\operatorname{support}\left(\mathrm{e}_{1}, \mathrm{e}_{2}, \ldots, \mathrm{e}_{\mathrm{n}}\right)=\left\|f_{1} \wedge f_{2} \wedge \ldots \wedge f_{n}\right\|
$$

then

$$
\begin{aligned}
& \text { support }\left(\left(\mathrm{e}_{1}, \mathrm{e}_{2,}, \ldots, \mathrm{e}_{\mathrm{n}}\right), \mathrm{e}_{\mathrm{n}+1}\right)= \\
& \|\left(\left(f_{1} \wedge f_{2} \wedge \ldots \wedge f_{n}\right) \wedge f_{n+1} \| .\right. \text { Q.E.D }
\end{aligned}
$$

Example 4.1: Let $\mathrm{I}=\{\mathrm{A}, \mathrm{B}, \mathrm{C}, \mathrm{D}, \mathrm{E}, \mathrm{F}\}$ be the set of all possible events in database D , where D is given in table 4.

| $I D$ | Transaction |
| :--- | :--- |
| 1 | ADCF |
| 2 | ABCD |
| 3 | ACEF |
| 4 | BCDE |
| 5 | CDEF |

Table 4
The corresponding Boolean matrix M is given in table 5.

| ID | A | B | C | D | E | F |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 1 | 1 | 0 | 1 | 1 | 0 | 1 |
| 2 | 1 | 1 | 1 | 1 | 0 | 0 |
| 3 | 1 | 0 | 1 | 0 | 1 | 1 |
| 4 | 0 | 1 | 1 | 1 | 0 | 0 |
| 5 | 0 | 0 | 1 | 1 | 1 | 1 |

## Table 5

The projection vectors of $\mathrm{A}, \mathrm{B}, \mathrm{C}, \mathrm{D}, \mathrm{E}$, and F are given in table 6.

The projection vectors of $\mathrm{AB}, \mathrm{BCD}$, and BDEF are given in table 7.

| 2 |

Table 7
The above Boolean expressions for calculating support using projection vectors could handle itemsets calculations where itemsets AB and BA are treated in the same way. For sequence database $D_{s}$, with maximum record length N , and by using the transaction mapping function discussed in section 3, event $A$ will be represented by items $\mathrm{A}_{\mathrm{i}}, 1 \leq \mathrm{i} \leq \mathrm{N}$. Projection vector

$$
f_{A}=\quad v^{1 \leq i \leq N}\left(f_{A_{i}}\right)
$$

Also, sequence AB will be represented by sequences $\mathrm{A}_{\mathrm{i}} \mathrm{B}_{\mathrm{j}}, 1 \leq \mathrm{i} \leq \mathrm{N}, \mathrm{i}<\mathrm{j} \leq \mathrm{N}$. Projection vector

$$
f_{A B}=\nu^{1 \leq i \leq N, i<j \leq N}\left(f_{A_{i}} \wedge f_{B_{j}}\right)
$$

Example 4.2: Let $\mathrm{I}=\{\mathrm{A}, \mathrm{B}, \mathrm{C}, \mathrm{D}\}$ be the set of all possible events in database D , where D is given in table 8. The association mapping of D is given in table 9 , and the corresponding Boolean matrix M is given in table 10 .

The projection vector of A, given in table 11, is the result of applying the Boolean operation $\vee$ on $f_{A_{1}}$ and $f_{A_{3}}$.

Lemma 4.3: For elements $e_{l}$ and $e_{k}$ in a sequence S , with projection vectors

$$
\left\{f_{l, 1}, f_{l, 2}, \ldots, f_{l, N}\right\} \text { and }\left\{f_{k, 1}, f_{k, 2}, \ldots, f_{k, N}\right\}
$$

respectively,

$$
\text { support }\left(e_{l}, e_{k}\right)=\left\|\quad \vee^{1 \leq i \leq N, i<j \leq N}\left(f_{e_{l, i}} \wedge f_{e_{k, j}}\right)\right\|
$$

Proof: Following the definition of Boolean operators, the proof of lemma 4.3 is straightforward.

Lemma 4.4: For elements $e_{1}, e_{2}, \ldots, e_{n}$ in a sequence database $\mathrm{D}_{\mathrm{S}}$, with projection vectors
$\left\{f_{1,1}, f_{1,2}, \ldots, f_{1, N}\right\},\left\{f_{2,1}, f_{2,2}, \ldots, f_{2, N}\right\}$, and $\left\{f_{n, 1}, f_{n, 2}, \ldots, f_{n, N}\right\}$ , respectively,

$$
\begin{gathered}
\operatorname{Support}\left(e_{1}, e_{2}, \ldots, e_{n}\right)= \\
\| \vee^{1 \leq i_{1} \leqslant N, i_{1}<i_{2} \leqslant N, \ldots, i_{n-1}<i_{n} \leqslant N}\left(f_{\left.e_{1, i_{1}} \wedge f_{e_{2, i_{2}}} \wedge \ldots \wedge f_{e_{n, i_{n}}}\right) \|} . \|\right.
\end{gathered}
$$

Proof: Following the definition of Boolean operators, the proof of lemma 4.4 is straightforward.
In this paper, we have modified the Apriori like algorithm to demonstrate the Boolean approach used for data mining. The approach is assuming that the mining problem is already in the association mining domain. For sequence mining, we should include two modules to the algorithm. The first module, maps the sequence database into an itemset database, while the second module maps back the association mining results into the sequence mining domain. The Boolean approach is given in figure 1.

Generate large itemsets using Boolean approach Input: Transaction database $D_{T}$
Output: large itemsets $L$
begin
for $\left(k=2 ; L_{k-1} \neq \emptyset ; K++\right)$
begin
$L_{k}=\varnothing$
$C_{k}=\operatorname{apriori}-\operatorname{gen}\left(L_{k-1}\right) ;$
for all c $\epsilon C_{k}$ do begin
calculate $f_{c}$ as given in lemma 4.4; $L_{k}=L_{k} \cup\left\{c \mid f_{c} \geq \operatorname{minsup}\right\} ;$ end;
end;
$L=U_{K} L_{K}$
end.

Fig. 1 Association Mining Using Boolean Approach

## $5 \quad$ Frequent Logical Expressions

In the previous section, we have shown that frequent items or frequent sequential patterns are represented by a logical expression. In order to maximize the performance of our technique, we need to minimize the generated Boolean expressions by using a suitable minimization technique.

Example 5.1: Using the Boolean matrix M in Table 10, with minimum support 2 , the resulted frequent sequences are

1-frequent sequences:

$$
\begin{aligned}
& \left(\mathrm{A}_{1} \vee \mathrm{~A}_{3} \vee \mathrm{~A}_{4}\right) \vee\left(\mathrm{B}_{1} \vee \mathrm{~B}_{2}\right) \vee\left(\mathrm{C}_{1} \vee \mathrm{C}_{2} \vee \mathrm{C}_{3}\right) \vee \\
& \left(\mathrm{D}_{2} \vee \mathrm{D}_{4} \vee \mathrm{D}_{5}\right)
\end{aligned}
$$

2- frequent sequences:

$$
\begin{aligned}
& \left(A_{1} \wedge C_{2}\right) \vee\left(A_{1} \wedge C_{3}\right) \vee\left(A_{1} \wedge C_{4}\right) \vee\left(A_{3} \wedge C_{4}\right) \vee\left(A_{1} \wedge D_{2}\right) \vee \\
& \left(A_{1} \wedge D_{4}\right) \vee\left(A_{1} \wedge D_{5}\right) \vee\left(A_{3} \wedge D_{4}\right) \vee\left(A_{3} \wedge D_{5}\right) \vee\left(A_{4} \wedge D_{5}\right) \vee \\
& \left(B_{1} \wedge A_{3}\right) \vee\left(B_{1} \wedge A_{4}\right) \vee\left(B_{2} \wedge A_{3}\right) \vee\left(B_{2} \wedge A_{4}\right) \vee\left(B_{3} \wedge A_{4}\right) \vee
\end{aligned}
$$

$\left(B_{1} \wedge D_{2}\right) \vee\left(B_{1} \wedge D_{4}\right) \vee\left(B_{1} \wedge D_{5}\right) \vee\left(B_{2} \wedge D_{4}\right) \vee\left(B_{2} \wedge D_{5}\right) \vee$
$\left(B_{3} \wedge D_{4}\right) \vee\left(B_{3} \wedge D_{5}\right) \vee\left(C_{1} \wedge A_{3}\right) \vee\left(C_{1} \wedge A_{4}\right) \vee\left(C_{2} \wedge A_{3}\right) \vee$
$\left(C_{2} \wedge A_{4}\right) \vee\left(C_{1} \wedge D_{2}\right) \vee\left(C_{1} \wedge D_{4}\right) \vee\left(C_{1} \wedge D_{5}\right) \vee\left(C_{2} \wedge D_{4}\right) \vee$
$\left(C_{2} \wedge D_{5}\right) \vee\left(C_{3} \wedge D_{4}\right) \vee\left(C_{3} \wedge D_{5}\right) \vee\left(D_{2} \wedge C_{3}\right)$

## 3- frequent sequences:

$$
\begin{aligned}
& \left(A_{1} \wedge D_{2} \wedge C_{3}\right) \vee\left(A_{1} \wedge D_{2} \wedge C_{4}\right) \vee\left(B_{1} \wedge A_{3} \wedge D_{4}\right) \vee\left(B_{1} \wedge A_{3} \wedge D_{5}\right) \vee \\
& \left(B_{2} \wedge A_{3} \wedge D 4\right) \vee\left(B_{2} \wedge A_{3} \wedge D_{5}\right) \vee\left(C_{1} \wedge A_{3} \wedge D_{4}\right) \vee\left(C_{1} \wedge A_{3} \wedge D_{5}\right) \vee \\
& \left.\left(C_{2} \wedge A_{3} \wedge D_{4}\right) \vee\left(C_{2} \wedge A_{3} \wedge D_{5}\right) \vee C_{3} \wedge A_{4} \wedge D_{5}\right)
\end{aligned}
$$

After doing hand Boolean minimization, the Boolean expression of frequent sequences in D is

$$
\begin{aligned}
& \left(A_{1} \wedge C_{2}\right) \vee\left(A_{3} \wedge C_{4}\right) \vee\left(A_{1} \wedge D_{4}\right) \vee\left(A_{1} \wedge D_{5}\right) \vee\left(B_{1} \wedge A_{4}\right) \vee \\
& \left(B_{2} \wedge A_{4}\right) \vee\left(B_{3} \wedge A_{4}\right) \vee\left(B_{1} \wedge D_{2}\right) \vee\left(B_{3} \wedge D_{4}\right) \vee\left(B_{3} \wedge D_{5}\right) \vee \\
& \left(C_{1} \wedge D_{2}\right) \vee\left(C_{3} \wedge D_{4}\right) \vee\left(C_{3} \wedge D_{5}\right) \vee\left(D_{2} \wedge C_{3}\right) \vee\left(A_{1} \wedge D_{2} \wedge C_{3}\right) \vee \\
& \left(A_{1} \wedge D_{2} \wedge C_{4}\right) \vee\left(B_{1} \wedge A_{3} \wedge D_{4}\right) \vee\left(B_{1} \wedge A_{3} \wedge D_{5}\right) \vee\left(B_{2} \wedge A_{3} \wedge D_{4}\right) \vee \\
& \left(B_{2} \wedge A_{3} \wedge D_{5}\right) \vee\left(C_{1} \wedge A_{3} \wedge D_{4}\right) \vee\left(C_{1} \wedge A_{3} \wedge D_{5}\right) \vee\left(C_{1} \wedge A_{4} \wedge D_{5}\right) \vee \\
& \left(C_{2} \wedge A_{3} \wedge D_{4}\right) \vee\left(C_{2} \wedge A_{3} \wedge D_{5}\right) \vee\left(C_{2} \wedge A_{4} \wedge D_{5}\right) \vee\left(C_{3} \wedge A_{4} \wedge D_{5}\right)
\end{aligned}
$$

Which can be written as
$(\mathrm{A} \wedge \mathrm{C}) \vee(\mathrm{A} \wedge \mathrm{D}) \vee(\mathrm{B} \wedge \mathrm{A}) \vee(\mathrm{B} \wedge \mathrm{D}) \vee(\mathrm{C} \wedge \mathrm{D}) \vee(\mathrm{D} \wedge \mathrm{C}) \vee$ $(\mathrm{A} \wedge \mathrm{D} \wedge \mathrm{C}) \vee(\mathrm{B} \wedge \mathrm{A} \wedge \mathrm{D}) \vee(\mathrm{C} \wedge \mathrm{A} \wedge \mathrm{D})$

Or
$\mathrm{AC}, \mathrm{AD}, \mathrm{BA}, \mathrm{BD}, \mathrm{CD}, \mathrm{DC}, \mathrm{ADC}, \mathrm{BAD}, \mathrm{CAD}$

The classical Karnaugh [15] maps approach could be used in minimizing Boolean expressions. The only problem of the Karnaugh maps approach is its limited task that is suited for at most 6 input variables and practical only for up to 4 variables. It is even harder to be carried out in product term sharing for multiple output functions. Also, the Karnaugh maps technique can not be automated in a computer program. In Boolean data mining solution, we are usually concerned with the large number of variables.

Quine and McCluskey [24] introduced the tabular method as the first alternative method to Karnaugh maps. It has two phases. It starts with the truth table for a set of logic expressions, a set of prime implicants is composed. In the second phase, A systematic procedure is followed to find the smallest set of prime implicants of output functions [19].

Although this Quine-McCluskey algorithm is very well suited to be implemented in a computer program.It produces the optimal logical expressions. The only problem we have with Quine-McCluskey algorithm is that it is not efficient in terms of processing time and memory usage. Increasing the number of variables by even one more variable to the function will double processing time and memory usage. The truth table length increases exponentially with the number of variables. So, the Quine-McCluskey method is practical only for functions with a limited number of input variables and output functions.
A different approach to this issue is the Espresso approach [13]. Instead of expanding a logic function into minterms, the approach processes cubes, representing the product terms. The output from this approach is not the optimum one, but it is very closely approximated, while the solution is always free from redundancy. This approach is more efficient than many of the other methods. It reduces memory computation time by several orders of magnitude. The important part of this approach is it has no restriction on the number of variables, output functions and product terms of a combinational function block. In our experimental study, we have used the Espresso approach for minimization.

## 6 Performance Study

In this section we present the performance results that have been collected. As a mining algorithm, we have used an Apriori-like algorithm as a local procedure to generate frequent itemsets (sequences). We would like to emphasize on the fact that our approach does not depend on the approach used to generate frequent itemsets.
We ran our experiments on a 2.4 GHz machine, with 4 GB of RAM and running windows Vista. The databases used were generated synthetically, to evaluate the performance of the algorithms over a range of data parameters. For 1000 distinct events (items), we assume that average value of the mapping factor for each event is set to 20 .
The range of database sizes is varied between 10,000 to 100,000 transactions. The results were evaluated against the BIDE algorithm [26], which is one of the latest algorithms designed for mining closed frequent sequences. Our study is based on the total mining time consumed for the whole data mining process. We have measured the mining time for the different database sizes on various minimum support values ranges between $0.2 \%$ and $5 \%$.
Figures 2, 3 and 4 show the execution times for the three synthetic databases of sizes $100,000,50000$, and 10000 transactions, respectively, for minimum support values varies from $0.5 \%$ to $5 \%$. As the minimum support decreases, the execution times of the two algorithms increase because of increases in the total number of candidate and large itemsets. In figures 2, 3, 4, the performance results are shown.
Figure 5 shows the execution times for minimum support value equals $1 \%$, and database sizes between 10000 and 100000 transactions. . As the database size increases, the execution times of all the algorithms increase because of increases in the total number of candidate and large itemsets. In figure 5, the performance results are shown.
It is clear that from the preliminary results depicted in figures 2-5, our implementation that is based on the Boolean approach has a better performance than the BIDE algorithm.

Fig. 2 Database Size is 100000 transactions

Fig. 3 Database Size is 50000 transactions

Fig. 4 Database Size is 10000 transactions

Fig. 5 Minimum Support equals $1 \%$

## 7 Conclusions

In this paper, we have proposed a new mapping function that maps event sequence into events set. Based on the unified representation of the association mining and the sequential pattern, a new approach that uses the Boolean representation of the input database D has been introduced, where database D is scanned only once to build a Boolean matrix $\mathrm{M} . \mathrm{M}$ has N columns and K rows, where N is the number of items in I , and K is the number of transactions in D . A position ( $\mathrm{i}, \mathrm{j}$ ) in M is 1 iff in transaction I, item $j$ exists, and 0 otherwise. Boolean algebra operations are applied on M to generate all frequent itemsets. Finally, frequent items or frequent sequential patterns has been represented by a logical expression that could be minimized by using a suitable logic function minimization technique. The Boolean approach does not depend on the association mining methodology. In this paper, we have used the apriori like algorithm for demonstrating the Boolean mining approach.
In the performance results, we have shown that our implementation that is based on the Boolean approach has a better performance than the BIDE algorithm.
