Abstract: In this paper we analyze an economical growth model with taxes and exponential utility in continuous and infinite time. This economical growth model leads to an optimal control problem. The necessary and sufficient conditions for optimality are given. Using the optimality conditions we prove the existence, uniqueness and stability of the study state for a differential equations system. Also we have investigated the dependence of the steady state \((k^*, c^*)\) on the growth rate of the labor force \(n\) and the effects of fiscal policy changes on welfare.

Key–Words: mathematical models applied in economies, endogenous growth, optimal policy

1 Introduction

In this paper, we consider a version of the Ramsey growth model with taxes in infinite and continuous time. This economy consists of a firm, a household and a government. The firm produces goods using two factors of production, capital and labor, it rents capital at the rate of interest \(r\) and it hires labor at the wage rate \(w\). Also, the firm seeks to maximize the present value of its profits. The government imposes taxes on capital and labor income, and it provides lump sum transfer and public-consumption expenditures. In this economy, the consumer chooses at any moment in time the level of consumption so as to maximize the global utility on the infinite time taking into account the budget constraint for household and the government. The utility function is given by an exponential function. This economical growth model leads to an optimal control problem. We prove that a necessary condition for the control function to solve our optimal control problem is that it is a solution of Euler equation. Also, we give the sufficient conditions for the optimal solution of the optimal control problem. An analogous result was formulated by Ş.Cruceanu and C. Vârsan [5]. Finally we investigate the effects of the fiscal policy changes on welfare. Some conclusions are given in section 7.

2 The economical growth model

In this paper, based on [1], [3], [2] and [8], we consider an economical growth model with public intervention. The economy consists of a household, a firm and a government. The competitive equilibrium achieved in a decentralized manner through perfect competition between the firm and the household. Also, we assume the economy closed (i.e. all of the stock capital must be owned by someone in economy and the net foreign debt is zero.)

The firm produces goods, pays wages for labor, and makes rental payments for capital on the competitive market at equilibrium prices given by the net marginal products of labor and capital.

Output is determined according to a constant returns to scale technology using the following production function

\[ Y = F(K, L) \] (1)

where \(K\) is the capital, \(L\) is the labor force, \(F : \mathbb{R}_+ \times \mathbb{R}_+ \to \mathbb{R}_+\) is a function of class \(C^2\) having the following properties

\[ \frac{\partial F(K, L)}{\partial K} > 0, \quad \frac{\partial F(K, L)}{\partial L} > 0, \forall K > 0, L > 0; \]
We define, taking
\[
F(K, L) = \lambda F(K, L) = \lambda Y, \forall \lambda > 0.
\]
Using the properties of function \( F \), given by
\[
\frac{\partial^2 F(K, L)}{\partial K^2} < 0, \quad \frac{\partial^2 F(K, L)}{\partial L^2} < 0, \forall K > 0, L > 0;
\]
\[
F(\lambda K, \lambda L) = \lambda F(K, L) = \lambda Y, \forall \lambda > 0;
\]
\[
\lim_{K \to 0} \frac{\partial F(K, L)}{\partial K} = \lim_{L \to 0} \frac{\partial F(K, L)}{\partial L} = 0
\]
\[
\lim_{K \to \infty} \frac{\partial F(K, L)}{\partial K} = \lim_{L \to \infty} \frac{\partial F(K, L)}{\partial L} = 0
\]
\[
F(K, 0) = F(0, L) = 0
\]
The firm seeks to maximize the present value of profits, given by
\[
Profit = F(K(t), L(t)) - (r(t) + \delta)K(t) - w(t)L(t),
\]
Taking \( r(t) \) and \( w(t) \) as given, \( r \) is the rental rate of capital, \( w \) is the wage per worker, and \( \delta \) is depreciation of capital.

We define
\[
k(t) = \frac{K(t)}{L(t)} - \text{the capital per worker};
\]
\[
y(t) = \frac{Y(t)}{L(t)} - \text{the output per worker}.
\]
Using the homogeneity condition we have
\[
Y = F(K, L) = L \cdot F\left(\frac{K}{L}, 1\right) = L \cdot f(k),
\]
where
\[
f(k) = F(k, 1).
\]
Then, the output per worker is
\[
y = f(k)
\]
Using the properties of function \( F \) we obtain the properties of function of class \( C^2 \), \( f : f(0) = 0; f'(k) > 0, f''(k) < 0, \forall k > 0; \lim f''(k) = \infty; \lim f'(k) = 0 \).

Profit for this firm can be written as
\[
Profit = L(t)(f(k(t)) - (r(t) + \delta)k(t) - w(t))
\]
The economical condition is that on a competitive market the maximum profit obtained by the firm is zero, and is given by
\[
f'(k) = r + \delta
\]
\[
f(k) - k f'(k) = w.
\]
We assume that the government taxes labor and net capital incomes at proportional rates \( \tau_w \) and \( \tau_r \). We also assume that the tax revenue is allocated between lump-sum transfer \( S \) and public consumption goods
\[
X. \text{ Assuming that the government must run a balanced budget at each moment in time and that tax rates, transfers, and public-consumption expenditures per unit of labor } (x = \frac{X}{T}, s = \frac{S}{T}) \text{ are constant over time, then we have the government budget constraint written in terms per capita}
\]
\[
\tau_r(f'(k) - \delta)k + \tau_w(f(k) - k f'(k)) = x + s
\]
where the left-hand side is the total tax revenue per unit of labor, and the right-hand side gives total expenditure. Given constant values of \( x + s \) and \( \tau_r \), equation can be solved for the value of \( \tau_w \) that will preserve budget balance for each value of \( k \).

In this economy the consumer chooses at any moment in time the level of consumption \( c(t) \) so that to maximize the global utility, given by
\[
U = -\frac{1}{\theta} \int_0^\infty e^{-(\rho-n)t} (1 - e^{-\theta c(t)}) dt,
\]
and subject to the budget constraint for the household, given by
\[
K(t) = (1 - \tau_r) r(t)K(t) + (1 - \tau_w) w(t)L(t) + S - C(t).
\]
Where \( c \) is the consumption, \( \rho > 0 \) is the discount rate and \( \theta > 0 \).

The size of the household grows at rate \( n \).
The budget constraint for the household can be rewritten in per capita terms as
\[
k(t) = (1 - \tau_r) r(t) k(t) + (1 - \tau_w) w(t) + s - c(t) - nk(t).
\]
where \( c(t) = \frac{C(t)}{L(t)} \) is the consumption per capita.

The initial stock of capital for the household is \( K_0 \). Thus, the initial stock of capital per capita is \( k_0 \).

In the conditions of a competitive equilibrium and taking into account the government budget constraint, the budget constraint for household in per capita terms can be rewritten as:
\[
k(t) = f(k(t)) - (n + \delta) k(t) - x - c(t).
\]

3 Determination of optimality conditions
The economical problem is to choose in every moment \( t \), the size of consumption so as to maximize the global utility taking into account the government budget constraint and the budget constraint for household and the initial stock of capital \( k_0 \), in the conditions
of competitive equilibrium, leads us to the following mathematical optimization problem (P):

**The problem P.** To determine \((k^*, c^*)\) which maximizes the following functional

\[
-\frac{1}{\theta} \int_0^\infty e^{-(\rho - n)t} (1 - e^{-\theta c(t)}) dt
\]

in the class of functions \(k \in AC([0, \infty), \mathbb{R}_+), \) and \(c \in \mathbb{X},\) where

\[
\mathbb{X} = \{c : [0, \infty) \rightarrow [0, A], c\text{--measurable}, A < \infty\}
\]

which verifies:

\[
\dot{k}(t) = f(k(t)) - (n + \delta)k(t) - x - c(t) \quad (9)
\]

\[
k(0) = k_0 \quad (10)
\]

In our problem \(P, k\) is the state variable and \(c\) is the control variable.

**Definition 1** A trajectory \((k(t), c(t))\) is called an admissible trajectory, with initial capital \(k_0,\) for the problem \((P)\) if it verifies the relation \((9)-(10).\)

**Definition 2** An admissible trajectory, \((k^*(t), c^*(t))\), is called optimal trajectory if:

\[
-\frac{1}{\theta} \int_0^\infty e^{-(\rho - n)t} (1 - e^{-\theta c(t)}) dt \leq \frac{1}{\theta} \int_0^\infty e^{-(\rho - n)t} (1 - e^{-\theta c^*(t)}) dt.
\]

for every admissible trajectory \((k(t), c(t))\) of the problem \((P).\)

In the following theorem we prove that a solution of our optimal control problem must satisfy a certain differential equation called the Euler equation. We denote:

\[
\phi(k(t)) = f(k(t)) - (n + \delta)k(t) - x. \quad (11)
\]

\[
U(c(t)) = -\frac{1}{\theta} (1 - e^{-\theta c(t)}) \quad (12)
\]

**Theorem 1** If \((c(t), k(t))\) is an optimal trajectory of the problem \((P),\) then it verifies the Euler-Lagrange equation:

\[
-\frac{d}{dt}(e^{-\theta c(t)} - (\rho - n)t) = e^{-\theta c(t)} - (\rho - n)t \phi'(k(t)).
\]

**Proof:** Let \((c(t), k(t))\) by an optimal trajectory of the problem \((P).\)

From \((9)\) and \((11),\) we have \(c(t) = \phi(k(t)) - k(t).\)

Choose \([T, T']\) such that \(\phi'(k(t))\) is continuous on \([T, T'].$ Let \(h\) by any \(C^2\)-function on \([T, T']\) which satisfies \(h(T) = h(T') = 0.\)

For each real number \(\alpha \in \mathbb{R},\) we define a new function \(k_1(t)\) by \(k_1(t) = k(t) + \alpha h(t),\) as in fig. 1

Note that if \(\alpha\) is small, the function \(k_1(t)\) is "near" the function \(k(t).\)

We define

\[
J_h(\alpha) = \int_T^{T'} U(\phi(k(t) + \alpha h(t)) - (k(t) + \alpha h(t))) e^{-(\rho - n)t} dt.
\]

Because \(k(t)\) is an optimal trajectory, we have

\[
\int_T^{T'} U(\phi(k(t)) - k(t)) e^{-(\rho - n)t} dt
\]

\[
\geq \int_T^{T'} U(\phi(k(t) + \alpha h(t)) - (k(t) + \alpha h(t))) e^{-(\rho - n)t} dt
\]

for all \(\alpha \in \mathbb{R}.\)

Thus, \(J_h(\alpha) \leq J_h(0)\) for all \(\alpha \in \mathbb{R}.\) Hence the function \(J_h(\alpha)\) has a maximum at \(\alpha = 0,\) so that

\[
J_h'(0) = 0. \quad (15)
\]

Now, looking at \((14),\) we see that to calculate \(J_h'(0)\) we must differentiate the integral with respect to a parameter appearing in the integrand.

Conversely, \((15)\) implies

\[
\int_T^{T'} U'(\phi(k(t)) - \dot{k}(t))(\phi'(k(t))h(t) - \dot{h}(t)) e^{-(\rho - n)t} dt = 0
\]

\[
(16)
\]
We consider 
\[
\psi(t) = \int_T^t U'(\phi(k(s)) - \dot{k}(s))\phi'(k(s))e^{-(\rho-n)s}ds,
\]
\[t \in [T, T']\]
and 
\[
g(t) = \psi(t) + G,
\]
where \(G\) is given by 
\[
\int_T^{T'} U'(\phi(k(t)) - \dot{k}(t))\phi'(k(t))h(t)e^{-(\rho-n)t}dt + G(T' - T) = 0
\]
Since 
\[
h(T) = h(T') = 0.
\]
we have 
\[
\int_T^{T'} \left( U'(\phi(k(t)) - \dot{k}(t))\phi'(k(t))h(t)e^{-(\rho-n)t} \right) dt = \int_T^T g(t)h(t)dt = -\int_T^{T'} g(t)\dot{h}(t)dt
\]
Thus, (16) it becomes:
\[
T' \int_T^T \left( g(t) + U'(\phi(k(t)) - \dot{k}(t))e^{-(\rho-n)t} \right) h(t)dt = 0,
\]
for all functions \(h\) which are \(C^1\) on \([T, T']\) and which satisfy \(h(T) = h(T') = 0\).

We consider 
\[
h(t) = -\int_T^{T'} \left( U'(\phi(k(s)) - \dot{k}(s))e^{-(\rho-n)s} + \psi(s) ds - G(t-T) \right)
\]
\[t \leq T'.\]
From (17) and the definition for \(g\) and \(G\), we obtain 
\[
\int_T^{T'} \left( g(t) + U'(\phi(k(t)) - \dot{k}(t))e^{-(\rho-n)t} \right) dt = 0.
\]
Thus 
\[
g(t) = -U'(\phi(k(t)) - \dot{k}(t))e^{-(\rho-n)t} \text{ for all } t \in [T, T'].
\]
Since \(g\) is a continuous function on \([T, T']\), we see that \(c(t) = \phi(k(t)) - k(t)\) is a continuous function on 
\([T, T']\) and \(\dot{g}\) is a continuous function on \([T, T']\).

Hence, we conclude 
\[
\dot{g}(t) = U'(\phi(k(t)) - \dot{k}(t))\phi'(k(t))e^{-(\rho-n)t} = -\frac{d}{dt} \left( U'(\phi(k(t)) - \dot{k}(t))e^{-(\rho-n)t} \right).
\]
This is the Euler-Lagrange equation discovered in 1744 by mathematician Euler.

In next theorem, we give the sufficient conditions for the solution of our optimal control problem \(P\).

**Theorem 2** Let \((k^*(t), c^*(t))\) be an admissible trajectory in problem \(P\). If there exists an absolutely continuous function \(q(t)\) such that for all \(t\), the following conditions are satisfied 
\[
\dot{q}(t) = q(t)(\rho - (f'(k(t)) - \delta)(1 - \tau)) \quad (18)
\]
\[
q(t) = e^{-\theta c^*(t)} \quad (19)
\]
\[
\lim_{t \to \infty} e^{-(\rho-n)t} q(t) = 0 \quad (20)
\]
then \((k^*(t), c^*(t))\) is an optimal trajectory in problem \(P\).

**Proof:** Let \((k^*(t), c^*(t))\) be an arbitrary admissible trajectory for \(P\).

We denote 
\[
\Delta = \int_0^\infty e^{-(\rho-n)t}(1-e^{-\theta c^*(t)}) dt - \int_0^\infty e^{-(\rho-n)t}(1-e^{-\theta c(t)}) dt
\]
and we define the function of Hamilton-Pontryagin 
\[H : [0, \infty) \times [0, A] \times \mathbb{R} \times [0, \infty) \to \mathbb{R},\]

given by 
\[
H(k, c, p, t) = \frac{1}{\theta}e^{-(\rho-n)t}(1-e^{-\theta c}) + p(f(k)-(n+\delta)k-c-x)
\]
\[\text{(22)}\]
In the following, we simplify our notation and put 
\[k^*(t) = k^*, \quad c^*(t) = c^* \quad x(k) = k, \quad c(t) = c, \quad H(k, c, p, t) = H, \quad H(k^*, c^*, p, t) = H^*.
\]
From (22) we have 
\[
\frac{1}{\theta}e^{-(\rho-n)t}(1-e^{-\theta c}) = H(k, c, p, t) - p(f(k)-(n+\delta)k-c-x)
\]
and using (9) the relation (21) becomes 
\[
\Delta = \int_0^\infty (H(k^*, c^*, p, t) - H(k, c, p, t)) dt + \int_0^\infty p(k-c) dt.
\]
\[\text{(23)}\]
Since 
\[
H''_{kk}(k, c, p, t) = pf''(k)
\]
\[
H'(c, k, p, t) = e^{-(\rho-n)t}e^{-\theta c} - p(t)
\]
\[
H''_{cc}(k, c, p, t) = -\theta e^{-(\rho-n)t}e^{-\theta c},
\]
we have that $H(k, c, p, t)$ is concave as a function of $c$ and $k$.
Using a standard result on concave functions, we obtain
$$H(k, c, p, t) - H(k^*, c^*, p, t) \leq \frac{\partial H^*}{\partial k}(k - k^*) + \frac{\partial H^*}{\partial c}(c - c^*).$$
(24)

Using the transformation $q(t) = e^{(\rho-n)t}p(t)$ in (18) we have the equation of the adjoint variable $p$,
$$\frac{\partial H^*}{\partial k} = -\dot{p}.$$  
Using (24) and $\frac{\partial H^*}{\partial k} = -\dot{p}$ in (23), we obtain that
$$\Delta \geq \int_0^\infty (p(k - k^*) + p(k - k^*))dt + \int_0^\infty \frac{\partial H^*}{\partial c}(c - c^*)dt.$$  
(25)

We differentiate (22) with respect to $c$ and using (19) we obtain the maximum condition
$$H(k^*(t), c^*(t), p(t), t) \geq H(k^*(t), c, p(t), t), \forall c \in [0, A]$$
i.e.
$$\frac{\partial H^*}{\partial c}(c^* - c) \geq 0, \forall c \in [0, A].$$  
(26)

From (26) we have that the second integral in (25) is $\geq 0$, so
$$\Delta \geq \int_0^\infty (p(k - k^*) + p(k - k^*))dt.$$  
(27)

or equivalently,
$$\Delta \geq \int_0^\infty \frac{d}{dt}(p(k - k^*))dt = p(k - k^*|_{0}^{\infty}.$$ 

Hence, using (20) we obtain the inequality
$$\frac{1}{\theta} \int_0^\infty e^{-\theta t}(1 - e^{-\theta t})(k - k^*)dt \geq \frac{1}{\theta} \int_0^\infty e^{-\theta t}(1 - e^{-\theta t})(k - k^*)dt,$$
which prove that $(k^*(t), c^*(t))$ is an optimal trajectory in problem $P$.

**Remark 3** The optimal trajectory of the problem $(P)$ in the conditions of a competitive equilibrium is the solution of the following system
$$\dot{k}(t) = f(k(t)) - (n + \delta)k(t) - x - c(t)$$  
(28)
$$\dot{c}(t) = -\frac{1}{\theta}[\rho - (1 - \tau_r)(f'(k(t)) - \delta)].$$  
(29)

\section{Qualitative analysis of the optimal solution}

**Proposition 4** The system of differential equations
$$\dot{k}(t) = f(k(t)) - (n + \delta)k(t) - x - c(t)$$  
(30)
$$\dot{c}(t) = -\frac{1}{\theta}[\rho - (1 - \tau_r)(f'(k(t)) - \delta)]$$  
(31)

exhibits saddle-path stability.

**Proof:** In order to determinate the steady state of the above system we choose the stationary solutions $k(t) = k^*, c(t) = c^*$. From $\dot{c}(t) = 0$ we obtain
$$f'(k) = \frac{\rho}{1 - \tau_r} + \delta.$$  
(32)

Using the properties of the function $f$, it results that the equation (32) has a unique solution $k = k^*$ with which we may determine
$$c^* = f(k^*) - (n + \delta)k^* - x.$$  
(33)

The point $(k^*, c^*)$ represents a steady state for the system of differential equations.

In order to investigate the stability of the steady state $(k^*, c^*)$ we linearize the system (30)-(31)in the steady state $(k^*, c^*)$ and we obtain
$$\dot{k}(t) \approx (f'(k^*) - n - \delta)(k(t) - k^*) - (c(t) - c^*)$$
$$\dot{c}(t) \approx \frac{1}{\theta}(1 - \tau_r)f''(k^*)(k(t) - k^*)$$

The matrix of the linearized system is
$$\begin{pmatrix} f'(k^*) - n - \delta & -1 \\ \frac{1}{\theta}(1 - \tau_r)f''(k^*) & 0 \end{pmatrix}.$$ 

The eigenvalues are solutions of equation
$$\lambda^2 - \lambda(f'(k^*) - n - \delta) + \frac{1}{\theta}(1 - \tau_r)f''(k^*) = 0.$$  
(34)

Because $f$ is a concave function, it results that the determinant of the equation is positive
$$\Delta = (f'(k^*) - n - \delta)^2 - 4\frac{1}{\theta}(1 - \tau_r)f''(k^*) > 0$$
and
$$p = \frac{1}{\theta}(1 - \tau_r)f''(k^*) < 0.$$ 

Hence, the equation (34) has two real roots for the contrary signs
$$\lambda_{1,2} = \frac{(f'(k^*) - n - \delta) \pm \sqrt{\Delta}}{2}.$$  
(35)
Using (32), it results that the relation (35) which gives the eigenvalues, can be written thus

$$\lambda_{1,2} = \frac{\rho}{1-\tau_r} \pm \sqrt{\frac{n}{2} - \frac{n}{2}}$$

The eigenvalues of the linearized system being the real numbers with contrary signs, it results that the steady state \((k^*, c^*)\) is the saddle point.

Because the steady state \((k^*, c^*)\) is saddle point, there are two manifolds passing through the steady state: a stable manifold \(W_s\) and an instable manifold \(W_i\). The dynamic equilibrium follows the stable manifold

**Theorem 3**

1) The eigenvector, corresponding to the eigenvalue

$$\lambda_1 = \frac{\rho}{1-\tau_r} - n + \sqrt{\frac{\rho}{1-\tau_r} - n^2 - \frac{4}{\theta}(1-\tau_r)f''(k^*)}$$

is given by

$$v_1 = \alpha(1, v_2), \alpha \in \mathbb{R}$$

where

$$\alpha(1, v_2) = \frac{\rho}{1-\tau_r} - n + \sqrt{\frac{\rho}{1-\tau_r} - n^2 - \frac{4}{\theta}(1-\tau_r)f''(k^*)} - \frac{n}{2}$$

2) The eigenvector, corresponding to the eigenvalue

$$\lambda_2 = \frac{\rho}{1-\tau_r} - n - \sqrt{\frac{\rho}{1-\tau_r} - n^2 - \frac{4}{\theta}(1-\tau_r)f''(k^*)}$$

is given by

$$v_2 = \omega(1, v_1), \omega \in \mathbb{R}$$

where

$$\omega(1, v_1) = \frac{\rho}{1-\tau_r} - n - \sqrt{\frac{\rho}{1-\tau_r} - n^2 - \frac{4}{\theta}(1-\tau_r)f''(k^*)} - \frac{n}{2}$$

**Proof:** The matrix of the linearized system is:

$$A(1, v_1) = \begin{pmatrix} f'(k^*) - (n + \delta) & -1 \\ \frac{1}{\theta}(1-\tau_r)f''(k^*) & 0 \end{pmatrix}$$

Its eigenvalues are the roots of the characteristic equation

$$\lambda^2 - tr.A\lambda + det.A = 0$$

where \(tr.A = f'(k^*) - (n+\delta) = \frac{\rho}{1-\tau_r} - n\) and \(det.A = \frac{1}{\theta}(1-\tau_r)f''(k^*)\).

So, the eigenvalues are given by

$$\lambda_1 = \frac{\rho}{1-\tau_r} - n - \sqrt{\left(\frac{\rho}{1-\tau_r} - n\right)^2 - \frac{4}{\theta}(1-\tau_r)f''(k^*)} < 0$$

and

$$\lambda_2 = \frac{\rho}{1-\tau_r} - n + \sqrt{\left(\frac{\rho}{1-\tau_r} - n\right)^2 - \frac{4}{\theta}(1-\tau_r)f''(k^*)} > 0$$

Next, we shall calculate the eigenvector \(v = (v_1, v_2)^T\) associated to the eigenvalue \(\lambda_1\). This vector is tangent in the steady state \((k^*, c^*)\) to the optimal trajectory.

The eigenvector is the solution of the equation

$$Av = \lambda_1 v, \quad v = (v_1, v_2)^T$$

Therefore,

$$\begin{pmatrix} f'(k^*) - n - \delta - \lambda_1 & -1 \\ \frac{1}{\theta}(1-\tau_r)f''(k^*) & -\lambda_1 \end{pmatrix} \begin{pmatrix} v_1 \\ v_2 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}$$

which means that

$$\begin{align*}
(f'(k^*) - n - \delta - \lambda_1)v_1 - v_2 &= 0 \\
\frac{1}{\theta}(1-\tau_r)f''(k^*)v_1 - \lambda_1 v_2 &= 0.
\end{align*}$$

Normalizing \(v_1 = 1\) and taking into account (32) we obtain \(v = (1, v_2)\), where

$$v_2 = \frac{\rho}{1-\tau_r} - n + \sqrt{\left(\frac{\rho}{1-\tau_r} - n\right)^2 - \frac{4}{\theta}(1-\tau_r)f''(k^*)} > 0$$

The slope of the stable manifold \(W_s\) in the steady state \((k^*, c^*)\) will be given by \(v_2\).

In the same way for the eigenvalue \(\lambda_2\) we obtain the associated eigenvector \(v = (1, v_2)\), where

$$\omega(1, v_1) = \frac{\rho}{1-\tau_r} - n - \sqrt{\left(\frac{\rho}{1-\tau_r} - n\right)^2 - \frac{4}{\theta}(1-\tau_r)f''(k^*)} < 0$$

The slope of the instable manifold \(W_i\) in the steady state \((k^*, c^*)\) will be given by \(\omega_2\).

5 The dependence of the steady state \((k^*, c^*)\) on the growth rate of the labor force \(n\)

**Proposition 5** The function \(c^*(n)\) is strictly decreasing with respect to \(n\) and \(k^*\) does not depend on \(n\).
Proof: Differentiating with respect to \( n \) the relation

\[
f'(k^*) = \frac{\rho}{1 - \tau_r} + \delta
\]

we obtain

\[
f''(k^*) \frac{dk^*}{dn} = 0
\]

consequently,

\[
\frac{dk^*}{dn} = 0.
\]

Therefore, because \( \frac{dk^*}{dn} = 0 \), \( k^*(n) \) does not depend on \( n \).

Differentiating with respect to \( n \) the relation

\[
c^* = f(k^*) - (n + \delta)k^* - x
\]

we obtain

\[
\frac{dc^*}{dn} = f'(k^*) \frac{dk^*}{dn} - (n + \delta) \frac{dk^*}{dn} - k^*
\]

or equivalently

\[
\frac{dc^*}{dn} = (f'(k^*) - n - \delta) \frac{dk^*}{dn} - k^*
\]

Because \( \frac{dk^*}{dn} = 0 \), we obtain \( \frac{dc^*}{dn} = -k^* < 0 \), therefore \( c^*(n) \) is strictly decreasing with respect to \( n \).

Due to the fact that the parameter \( n \) represents the growth rate of labor force, the result of the above theorem from an economic point of view, would be interpreted as following: the optimum level of capital is not influenced by labor force and if the labor force would grow in time then the optimum level of consumption per capita would shrink in time as well. A reduction of labor force would lead to a rise in the optimum consumption level per capita.

6 Change in Public Policy

We will study the effects of a tax change. We suppose that the economy is initially at the steady state corresponding to the given values of the different tax parameters. Also, we suppose that the government changes the tax rate on interest income from the initial value \( \tau_r \) to a new one \( \tau_{r_1} \), keeping total expenditure per unit of labor \( s + x \) constant, and adjusting the tax rate on wage income \( \tau_w \) as needed to preserve budget balance at any moment in time.

In the following, we will determine the effects of the fiscal policy change on the steady-state values of capital \( k \) and consumption \( c \), given by the solution of the system

\[
\dot{c}(t) = 0 \iff f'(k) = \frac{\rho}{1 - \tau_r} + \delta \quad (36)
\]

\[
\dot{k}(t) = 0 \iff c = f(k) - (n + \delta)k - x \quad (37)
\]

Let \((k^*, c^*)\) be the steady state value of the capital \( k \) and the consumption \( c \).

Proposition 6 The function \( k^*(\tau_r) \) is strictly decreasing with respect to \( \tau_r \).

Proof: Due to the relation (36), \( k^* \) verifies

\[
f'(k^*) = \frac{\rho}{1 - \tau_r} + \delta. \quad (38)
\]

Differentiating with respect to \( \tau_r \) on both members of the relation (38) we obtain

\[
f''(k^*) \frac{dk^*}{d\tau_r} = \frac{\rho}{(1 - \tau_r)^2}.
\]

Hence, we have

\[
\frac{dk^*}{d\tau_r} = \frac{1}{f''(k^*)} \frac{\rho}{(1 - \tau_r)^2}.
\]

This equality and the fact that the function \( f \) is strictly concave imply

\[
\frac{dk^*}{d\tau_r} < 0.
\]

Therefore, \( k^*(\tau_r) \) is strictly decreasing with respect to \( \tau_r \).

With \( x \) fixed, the position of the \( k = 0 \) line does not depend on the value of \( \tau_r \).

According to the Proposition 6, we have that a decrease in \( \tau_r \) increases the steady-state value of the capital from the initial value \( k^* \) to a new one \( k^*_1 \) and shifts the \( \dot{c}(t) = 0 \) isocline to the right, determining the new steady-state value of the consumption, as in fig. 2.

The effect on consumption depends on the slope of the \( \dot{k}(t) = 0 \) isocline at the steady state \((k^*, c^*)\), given by

\[
c'(k^*) = f'(k^*) - (n + \delta) = \frac{\rho}{1 - \tau_r} - n \quad (39)
\]

Because \( c'(k^*) > 0 \), we obtain that a decrease in \( \tau_r \) will grow the steady state value of consumption from the initial value \( c^* \) to a new one \( c^*_1 \).

Therefore, a decrease in \( \tau_r \) encourages accumulation by growing the net return on saving. In the long run, therefore, the capital is an decreasing function of \( \tau_r \).
Because the steady state utility, given by
\[ u(c^*) = -\frac{1}{\theta} \int_0^\infty e^{-(\rho-n)t} e^{-\theta c^*} dt = -\frac{1}{\theta (\rho-n)} e^{-\theta c^*} \]
is a decreasing function of steady state consumption, decreases in \(\tau_r\) will grow steady state value of consumption and therefore will grow welfare.

In order to calculate the net changes upon welfare, we shall evaluate the utility function with respect to the tax rate on interest income \(\tau_r\). For this we define
\[ V(\tau_r) = \frac{1}{\theta} \int_0^\infty e^{-(\rho-n)t} \left(1 - e^{-\theta c(t)}\right) dt \]  
(40)
which expresses the global utility of the representative household as a function of the tax rate on interest income \(\tau_r\).

\(c_t(\tau_r)\) represents the consumption along the stable manifold of the system
\[ \dot{k}(t) = f(k(t)) - (n + \delta)k(t) - c(t) - x \]  
(41)
\[ \dot{c}(t) = -\frac{1}{\theta} [\rho - (1 - \tau_r)(f'(k(t)) - \delta)] \]  
(42)
corresponding to a given value of the tax rate on interest income \(\tau_r\).

The stable manifold of the system (41)-(42) can be looked as the graph of the function
\[ c = p(k, \tau_r) \]  
(43)
which expresses the equilibrium value of consumption \(c\) as a function of the current value of the capital \(k\) and the tax rate on interest income \(\tau_r\). This relation is known in dynamic programming as a policy function: it relates the optimal value of a control variable to the state variable.

Because the slope of the stable manifold at the steady state is negative, being given by the slope of the stable eigenvector corresponding to the negative eigenvalue \(\lambda_1\)
\[ p_k = v_2 = \frac{1}{2} \left( \frac{\rho}{1 - \tau_r} - n \right) + \]  
(44)
\[ + \frac{1}{2} \sqrt{\left( \frac{\rho}{1 - \tau_r} - n \right)^2 - \frac{4}{\theta} (1 - \tau_r) f''(k^*)} \]
we have that an increases of the tax rate on interest income \(\tau_r\) will shift the manifold upward.

Thus,
\[ p_{\tau_r} > 0. \]  
(45)
Substituting the policy function into the evolution equation of the capital, the relation (41), we obtain the evolution equation of the capital along the stable manifold
\[ \dot{k}(t) = f(k(t)) - (n + \delta)k(t) - p(k(t), \tau_r) - x = \]  
\[ \chi(k(t), \tau_r). \]  
(46)
This equation has a unique steady state that coincides with the steady state of the system (41)-(42).

Taking into account (44) and (46), we have
\[ \chi_k(k^*, \tau_r) = -p_k(k^*, \tau_r) + \]  
(47)
\[ + \left( f'(k^*) - n - \delta \right) = \lambda_1 < 0 \]
therefore, that the steady state is stable.

The solution of the differential equation (46), denote with \(k_t(\tau_r)\), us give the equilibrium value of \(k\) as a function of time and the tax rate on interest income \(\tau_r\).

\[ k_t(\tau_r) = \frac{p_k(k_t(\tau_r), \tau_r)}{1 - \tau_r} \]  
(48)
In order to analyze the effect of the tax rate on interest income \(\tau_r\) on the consumption we will calculate the marginal change in consumption at the moment \(t\), so that:
\[ \frac{dc_t(\tau_r)}{d\tau_r} = p_k(k_t(\tau_r), \tau_r) \frac{dk_t(\tau_r)}{d\tau_r} + p_{\tau_r}(k_t(\tau_r), \tau_r). \]  
(49)
The solution of the equation (46), \(k_t(\tau_r)\), must satisfy the equation (41)
\[ \dot{k}(t, \tau_r) = f(k(t, \tau_r)) - (n + \delta)k(t, \tau_r) - p(k(t, \tau_r), \tau_r) - x \]  
(50)
where we denote $k_1(\tau_r) = k(t, \tau_r)$.

Differentiating the equation (50) with respect to $\tau_r$ and taking into account the fact that $k_{\tau_r}(t, \tau_r) = \frac{dk_{\tau_r}}{dt}(t, \tau_r)$, we have:

$$
\frac{dk_{\tau_r}}{dt}(t, \tau_r) = f'(k(t, \tau_r)) \frac{dk}{d\tau_r}(t, \tau_r) - (n + \delta) \frac{dk}{d\tau_r}(t, \tau_r) - p_k(k(t, \tau_r), \tau_r) \frac{dk}{d\tau_r}(t, \tau_r) - p_r(k(t, \tau_r), \tau_r)
$$

The equation (51) can be rewritten at the steady state such as:

$$
\frac{dk_{\tau_r}}{dt}(t, \tau_r) = \lambda_1 \frac{dk}{d\tau_r}(t, \tau_r) - p_r(k^*, \tau_r)
$$

or equivalent with

$$
k_{\tau_r}(t) = \lambda_1 k_{\tau_r}(t) - p_r(k^*, \tau_r)
$$

which is a differential equation with constant coefficients.

The general solution of the differential equation (52) is given by:

$$
k_{\tau_r}(t) = e^{\lambda_1 t} k_{\tau_r}(0) + \left(1 - e^{\lambda_1 t}\right) \frac{p_r(k^*, \tau_r)}{\lambda_1}
$$

Because $\lambda_1 < 0$, the steady state value of this equation is stable and $k_{\tau_r}$ asymptotically converges at the steady state value, given by:

$$
k^*_r = \frac{p_r(k^*, \tau_r)}{\lambda_1} < 0
$$

which is the derived of the steady state value of the capital $k$ with respect to $\tau_r$.

Due to the fact that $k_{\tau_r}(0)$ is predetermined, it results that the changes in $\tau_r$ do not produce changes in $k_{\tau_r}(0)$.

Hence, the trajectory of the capital $k_{\tau_r}$ is given by:

$$
k_{\tau_r}(t) = \left(1 - e^{\lambda_1 t}\right) \frac{p_r(k^*, \tau_r)}{\lambda_1}
$$

From the equation (55), we note that a reduction in the tax rate of interest income $\tau_r$ determines a reduction of capital $k$, towards the new value of the steady state, at an exponential rate given by the stable root of the system.

Substituting (55) in (49), we can calculate the derived of the consumption trajectory as function of $\tau_r$:

$$
\frac{dc_t(\tau_r)}{d\tau_r} = p_k(k^*, \tau_r) \frac{1 - e^{\lambda_1 t}}{\lambda_1} \frac{p_r(k^*, \tau_r)}{\lambda_1} + (56)
$$

using (47), (39) and (45) in (56) we obtain:

$$
\frac{dc_0(\tau_r)}{d\tau_r} = p_r > 0, \quad (57)
$$

Using (47), (39) and (45) in (56) we obtain:

$$
\frac{dc_\infty(\tau_r)}{d\tau_r} = p_r \left(\frac{p_k}{\lambda_1} + 1\right) = \frac{p_r}{\lambda_1} \left(\frac{p_k + 1}{\lambda_1}\right) = \frac{p_r}{\lambda_1} \left(\frac{\rho}{1 - \tau_r} - n\right) < 0.
$$

Considering the relation (57) we obtain that the immediate effects of fiscal policy consist of the growth of consumption per capita, which determines the shift of the optimal trajectory upwards. Considering the relation (58) we obtain that the long term effects consist in the reduction of consumption per capita until the reach of the new steady state value.

The relations (57)-(58) show that an increase in the tax rate of the interest income $\tau_r$ will discourage the accumulation due to the reduction of the net income rate, which will consequently encourage the short-term consumption, thus, on the long-term, the capital will be reduced, a reduction which will determine a reduction of consumption on the long-term.

Next, we shall analyze the effects of the change of income rate of capital $\tau_r$ over social welfare.

Differentiating with respect to $\tau_r$

$$
V(\tau_r) = \frac{1}{\theta} \int_0^\infty e^{-(\rho - n)t} \left(1 - e^{-\theta c_t(\tau_r)}\right) dt
$$

evaluated in the steady state and using (56), we obtain
\[ V' (\tau_k) = e^{-\theta c^*} \int_0^\infty e^{-(\rho-n)t} \frac{dc_t (\tau_r)}{d\tau_r} dt = (60) \]

\[ = e^{-\theta c^*} \int_0^\infty e^{-(\rho-n)t} p_{\tau_r} \left( (1-e^{\lambda_t t}) \frac{p_k}{\lambda_1} + 1 \right) dt = \]

\[ = e^{-\theta c^*} p_{\tau_r} \int_0^\infty e^{-(\rho-n)t} \left( \frac{p_k + \lambda_1}{\lambda_1} - e^{\lambda_t t} \frac{p_k}{\lambda_1} \right) dt = \]

\[ = e^{-\theta c^*} p_{\tau_r} \frac{p_k + \lambda_1}{\lambda_1} \int_0^\infty e^{-(\rho-n)t} dt - \]

\[ - e^{-\theta c^*} p_{\tau_r} \frac{p_k}{\lambda_1} \int_0^\infty e^{-(\rho-n)t} e^{\lambda_t t} dt = \]

\[ = e^{-\theta c^*} p_{\tau_r} \left( \frac{p_k + \lambda_1}{\rho - n} - \frac{p_k}{\rho - n - \lambda_1} \right) = \]

\[ = e^{-\theta c^*} p_{\tau_r} \left( \frac{p_k + \lambda_1}{\rho - n} - \frac{p_k}{\rho - n - \lambda_1} \right). \]

Using (47) and (39) in (60), we obtain

\[ V'' (\tau_r) = e^{-\theta c^*} p_{\tau_r} \frac{\rho - n - \frac{1}{1 - \tau_r}}{(\rho - n)(\rho - n - \lambda_1)} = \]

\[ = e^{-\theta c^*} p_{\tau_r} \frac{1}{\rho - n - \lambda_1} 1 - \tau_r. \quad (61) \]

Because \( p_{\tau_r} > 0, \lambda_1 < 0 \) and \( \rho > n \), we have \( V'' (\tau_r) < 0 \). Therefore, the welfare is strictly decreasing function as function of the tax rate on interest income \( \tau_r \).

Hence, we have that the optimal policy is that the tax rate on interest income \( \tau_r \) be zero.

7 Conclusion

In this paper we have analyzed an economic growth model with taxes in which the utility is given by exponential function. This economic growth model leads us to an optimal control problem. We have determined the necessary and sufficient conditions for optimality. Using these conditions, we have shown that the optimal trajectory for the optimal control problem is the solution for a differential equations system. We have proven the existence, uniqueness and stability of the study state for a differential equations system. We have shown that the optimum level of capital is not influenced by labor force and if the labor force would grow in time then the optimum level of consumption per capita would shrink in time as well. We have investigated the effects of the fiscal policy changes on the steady-state values of the capital and consumption, and on welfare. We have shown that a decrease in tax rate on interest income \( \tau_r \) encourages accumulation by growing the net return on saving. On the long run, therefore, the capital is a decreasing function of \( \tau_r \). Also, we have shown that a decrease in tax rate on interest income \( \tau_r \) will grow the welfare.
