Abstract: An Efficient Particle Swarm Optimization (EPSO) technique, employed to solve Economic Dispatch (ED) problems including losses in power system is presented in this paper. With practical consideration, ED will have nonsmooth cost functions with equality and inequality constraints that make the problem, a large-scale highly constrained nonlinear optimization problem. The proposed method expands the original PSO to handle a different approach for satisfying those constraints. In this paper, an Efficient Particle Swarm Optimization (EPSO) technique is employed so that faster convergence is obtained for the same results published in IEEE Proceedings. To demonstrate the effectiveness of the proposed method it is being applied to test ED problems, one with smooth and other with non smooth cost functions considering valve-point loading effects. Comparison with other optimization techniques showed the superiority of the proposed EPSO approach and confirmed its potential for solving nonlinear economic load dispatch problems with losses.

Key-words: Economic load dispatch, Particle swarm optimization, Valve point loading effect

1 Introduction
Economic Dispatch (ED) problem is one of the fundamental issues in power system operation. In essence, it is an optimization problem and its main objective is to reduce the total generation cost of units, while satisfying constraints. Previous efforts on solving ED problems have employed various mathematical programming methods and optimization techniques excluding losses [1]. Recently, Eberhart and Kennedy suggested a Particle Swarm Optimization (PSO) based on the analogy of swarm of bird and school of fish. In PSO, each individual makes its decision based on its own experience together with other individual’s experiences [2].
The individual particles are drawn stochastically towards the position of present velocity of each individual, their own previous best performance, and the best previous performance of their neighbors. The main advantages of the PSO algorithm are summarized as: simple concept, easy implementation, and computational efficiency when compared with mathematical algorithm and other heuristic optimization techniques. The practical ED problems with valve-point loading effects are represented as a non smooth optimization problem with equality and inequality constraints. To solve this problem, many salient methods have been proposed such as dynamic programming, evolutionary programming, neural network approaches, and genetic algorithm. In this paper, an alternative approach is proposed to the non smooth ED problem using an Efficient PSO (EPSO), which focuses on the treatment of the equality and inequality constraints when modifying each individual’s search. The equality constraint (i.e., the supply/demand balance) is easily satisfied by specifying a variable (i.e., a generator output) at random in each iteration as a slag generator whose value is determined by the difference between the total system demand (including losses) and the total generation excluding the slag generator. However, the inequality constraints in the next position of an individual produced by the PSO algorithm can violate the inequality constraints. In this case, the position of any individual violating the constraints is set to maximum or minimum depending on velocity evaluated [5].

2 Formulation of ED Problem
2.1 ED Problem with Smooth Cost Functions
Economic load dispatch (ELD) pertains to optimum generation scheduling of available generators in an interconnected power system to minimize the cost of generation subject to relevant system constraints. Cost equations are obtained from the heat rate characteristics of the generating machine. Smooth costs functions are linear, differentiable and convex functions.

The most simplified cost function of each generator can be represented as a quadratic function as given in whose solution can be obtained by the conventional mathematical methods [1]:

\[ C = \sum F_j(P_j) \quad (1) \]

\[ F_j(P_j) = a_j + b_j P_j + c_j P_j^2 \quad (2) \]

where
C total generation cost
Fj cost function of generator j
aj bj cj cost coefficients of generator j
Pj power output of generator j

While minimizing the total generation cost, the total generation should be equal to the total system demand plus the transmission network loss.

The transmission loss is given by the equation,

\[ P_L = \sum B_{ao}P_j \]

where \( B_{ao} \) is the loss co-efficient matrix.

The equality constraint for the ED problem can be given by,

\[ \sum P_j + P_L = D \quad (2) \]

where \( D \) is the total demand needed by the load or consumer.

The generation output of each unit should be between its minimum and maximum limits. That is, the following inequality constraint for each generator should be satisfied

\[ P_{j\min} < P_j < P_{j\max} \quad (3) \]

where \( P_{j\min}, P_{j\max} \) are the minimum and maximum output of individual generators.

2. ED Problem with Non-smooth Cost Functions
In reality, the objective function of an ED problem has non differentiable points according to valve-point effects. Therefore, the objective function should be composed of a set of non-smooth cost functions. In this paper, one case of non-smooth cost function is considered i.e. the valve-point loading problem where the objective function is generally described as the superposition of sinusoidal functions and quadratic functions [7].

2.2.1 Non-smooth Cost Function with Valve-Point Effects
The generator with multi-valve steam turbines has very different input-output curve compared with the smooth cost function[6]. Typically, the valve point results in, as each steam valve starts to open, the ripples like in to take account for the valve-point effects, sinusoidal functions are added to the quadratic cost functions as follows:

\[ F_j(P_j) = a_j + b_j P_j + c_j P_j^2 + e_j \times \sin(f_j \times (P_{j\min} - P_j)) \quad (4) \]

where \( e_j, f_j \) are the coefficients of generator j reflecting valve-point effects.
3. Implementation of PSO for ED Problems

The PSO algorithm searches in parallel using a group of individuals, in a physical dimensional search space, the position and velocity of individual $i$ are represented as the vectors $X_i = (x_{i1}, ..., x_{in})$ and $V_i = (v_{i1}, ..., v_{in})$ respectively, in the PSO algorithm. Let $P_{best_i} = (x_{i1}^{pbest}, ..., x_{in}^{pbest})$ and $G_{best_i} = (x_{i1}^{gbest}, ..., x_{in}^{gbest})$ respectively, be the position of the individual $i$ and its neighbors’ best position so far[2]. Using the information, the updated velocity of individual $i$ is modified under the following equation in the PSO algorithm:

$$V_{i}^{k+1} = \omega V_{i}^{k} + c_1 r_{a1} \times (P_{best_i}^{k} - X_{i}^{k}) + c_2 r_{a2} \times (G_{best}^{k} - X_{i}^{k})$$

where

- $V_{i}^{k}$ velocity of individual of iteration at $k$
- $\omega$ weight parameter
- $c_1, c_2$ acceleration factors
- $r_{a1}, r_{a2}$ random numbers between 0 and 1.
- $X_{i}^{k}$ position of individual $i$ at iteration $k$
- $P_{best_i}^{k}$ best position of individual $i$ throughout iteration $k$
- $G_{best}^{k}$ best position of group throughout iteration $k$

Each individual moves from the current position to the next one by the modified velocity in (7) using the following equation [2]:

$$X_{i}^{k+1} = X_{i}^{k} + V_{i}^{k+1}$$

The search mechanism of the PSO using the modified velocity and position of the individual $i$ based on (7) and (8) is illustrated in Fig. 2.

3.1 Efficient PSO for ED problems

In this section, a new approach to implement the PSO algorithm will be described while solving the ED problems considering losses. The main process of the efficient PSO algorithm can be summarized as follows:

**Step 1)** Initialization of a group at random while satisfying constraints.

**Step 2)** Velocity and position updates while satisfying constraints

**Step 3)** Update of Pbest and Gbest.

**Step 4)** Calculate transmission losses for the obtained Pbest and Gbest

**Step 5)** Increment the demand with the transmission losses

**Step 6)** Go to Step 2 until satisfying stopping criteria.

In the subsequent sections, the detailed implementation strategies of the EPSO are described.

3.1.1 Initialization of Individuals

In the initialization process, a set of individuals (i.e., generation outputs) is created at random. Therefore, individual $i$’s position at iteration 0 can be represented as the vector of

$$X_{i}^{0} = (P_{i1}^{0}, ..., P_{in}^{0})$$

where $n$ is the number of generators.

The velocity of individual $i$ is given by

$$V_{i}^{0} = (v_{i1}^{0}, ..., v_{in}^{0})$$

corresponds to the generation update quantity covering all generators. The following procedure is suggested for satisfying constraints for each individual in the group:
Step 1) Set j=1, i=1
Step 2) Select the jth element (i.e., generator) of an individual i.
Step 3) Create the value of the element (i.e., generation output) at random satisfying its inequality constraint.
Step 4) If j=n-1 then go to step 5; otherwise j=j+1 and go to Step 2.
Step 5) The value of the last element of an individual is determined by subtracting $\sum P_{ij}^0$ from the total demand.
Step 6) If i=no of individuals go to step 7; otherwise put i=i+1 and go to step 2.
Step 7) Stop the initialization process.

After creating the initial position of each individual, the velocity of each individual is also created at random. The following strategy is used in creating the initial velocity:

\[(P_{min}-\varepsilon)P_{ij}^0<V_{ij}^0<(P_{max}-\varepsilon)P_{ij}^0\]  \hspace{1cm} (9)

where $\varepsilon$ is a small positive real number.

The velocity of element j of individual i is generated at random within the boundary [2]. The initial Pbest, of i-th individual is set as the initial position of individual and the initial Gbest is determined as the position of an individual with minimum payoff of (1).

3.1.2 Velocity Update
To modify the position of each individual, it is necessary to calculate the velocity of each individual in the next stage, which is obtained from (7). In this velocity updating process, the values of parameters such as w, c1 and c2 should be determined in advance.

The weighting function is defined as follows:

\[w=w_{max}*(w_{max}-w_{min}/iter_{max})^*iter\]  \hspace{1cm} (10)

where
- $w_{max}$ final weight
- $w_{min}$ initial weight
- $iter_{max}$ maximum iteration number
- $iter$ current iteration number

3.1.3 Position Modification Considering Constraints
The position of each individual is modified by (8). The resulting position of an individual is not always guaranteed to satisfy the inequality constraints due to over/under velocity [4]. If any element of an individual violates its inequality constraint due to over/under speed then the position of the individual is fixed to its maximum or minimum operating point. Therefore, this can be formulated as follows:

\[
\begin{align*}
    P_{ij}^{k+1} &= \begin{cases} 
    P_{ij}^k + v_{ij}^{k+1} & \text{if } P_{ij}^k + v_{ij}^{k+1} \leq P_{ij}^{min} \\
    P_{ij}^{min} & \text{if } P_{ij}^k + v_{ij}^{k+1} > P_{ij}^{max} \\
    P_{ij}^{max} & \text{if } P_{ij}^k + v_{ij}^{k+1} > P_{ij}^{max} 
    \end{cases}
\end{align*}
\]  \hspace{1cm} (11)

To resolve the equality constraint problem without intervening the dynamic process inherent in the PSO algorithm, we propose the following heuristic procedures:

Step 1) Set j=1, i=1. Let the present iteration be k.
Step 2) Select the jth element (i.e., generator) of an individual i.
Step 3) Modify the value of element j using (7), (8), and (11). And satisfy inequality constraint.
Step 4) If j=n-1 then go to Step 5, otherwise j=j+1 and go to Step 2.
Step 5) The value of the last element of an individual is obtained by subtracting $\sum P_{ij}^0$ from the total system demand.
Step 6) If i=no. of individuals then go to step 7; otherwise i=i+1 and go to Step2
Step 7) Stop the modification procedure

3.1.4 Update of Pbest and Gbest
The Pbest of each individual at iteration k+1 is updated as follows:

\[
P_{best_i}^{k+1} = \begin{cases} 
    X_i^{k+1} & \text{if } TC_i^{k+1} < TC_i^k \\
    P_{best_i}^k & \text{if } TC_i^{k+1} \geq TC_i^k 
    \end{cases}
\]

Where
- $TC_i$ - the object function evaluated at the position of individual i

Additionally, Gbest at iteration k+1 is set as the best evaluated position among $P_{best_i}^{k+1}$

4 Simulated Result Analyses
To assess the efficiency of the proposed EPSO, it has been applied to ED (with losses) problems where the objective functions can be either smooth or non-smooth.

4.1 ED Problem with Smooth Cost Functions
The EPSO is applied to an ED problem for standard 2 unit system. The input data for the above system[1] is given in Table 1 and where PD is the power demand of the system in megawatt (MW). Table 2 shows the comparison of the results between EPSO and lambda iteration.
Software platform used: MATLAB 7.0

4.1.1 Two unit system Input Data:
Table 1:

<table>
<thead>
<tr>
<th>Unit</th>
<th>a_i</th>
<th>b_i</th>
<th>c_i</th>
<th>P_jmin</th>
<th>P_jmax</th>
<th>PD</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>400</td>
<td>5</td>
<td>0.01</td>
<td>20</td>
<td>200</td>
<td>250</td>
</tr>
<tr>
<td>2</td>
<td>600</td>
<td>4</td>
<td>0.015</td>
<td>20</td>
<td>200</td>
<td></td>
</tr>
</tbody>
</table>

PSO Parameters:
Generations= 100
Population size= 10
Maximum inertia weight, \( w_{max} = 0.9 \) Minimum inertia weight, \( w_{min} = 0.4 \) Acceleration Constants, \( c_1 = c_2 = 2 \)

Table 2:
Comparison Between EPSO With Losses And Lambda Iteration For 2-Unit Systems.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

As seen from Table 2, the EPSO has provided an efficient result when compared with that of iteration method.

4.1.2 Three unit system
The input data for the standard 3 unit system [1] is given in Table 3. As seen in Table 4, the EPSO has provided the global solution with a very high probability, compared with the lambda-iteration method [3], exactly satisfying the equality and inequality constraints.

Table 3:
Input Data For 3 Unit System

5. Conclusion

This paper presents a new approach to non-smooth ED problems based on the EPSO algorithm. A new strategy is incorporated in the PSO framework in order to provide the solutions satisfying the equality and inequality constraints. Although the proposed EPSO algorithm had been successfully applied to ED with valve-point loading effect, the practical ED problems should consider multiple fuels as well as prohibited operating zones. Finally we have obtained a rapid and efficient convergence for both smooth and non-smooth cost functions using this EPSO (with Transmission Losses) method as compared to various other conventional and non-conventional soft computing techniques.
